Generic 3 Station Vacuum Loader

This is an example of a three station loading system modeled after a motorized cam switch control. In such a system a series of cam-actuated switches turned by a shaded pole motor is driven when no stations require load. When one does (as sensed by closing a level switch) the cam switch stops at that station, and waits for the fill timer to complete before continuing.

- This example has two unusual features:
1. a 'proportional' low level control for station 1, and
 2. a method to prevent station 2 from loading unless station 1 is full.

Station Sequencer
 Reset the sequencer counter to station 1 if out-of-bounds value somehow occurs.

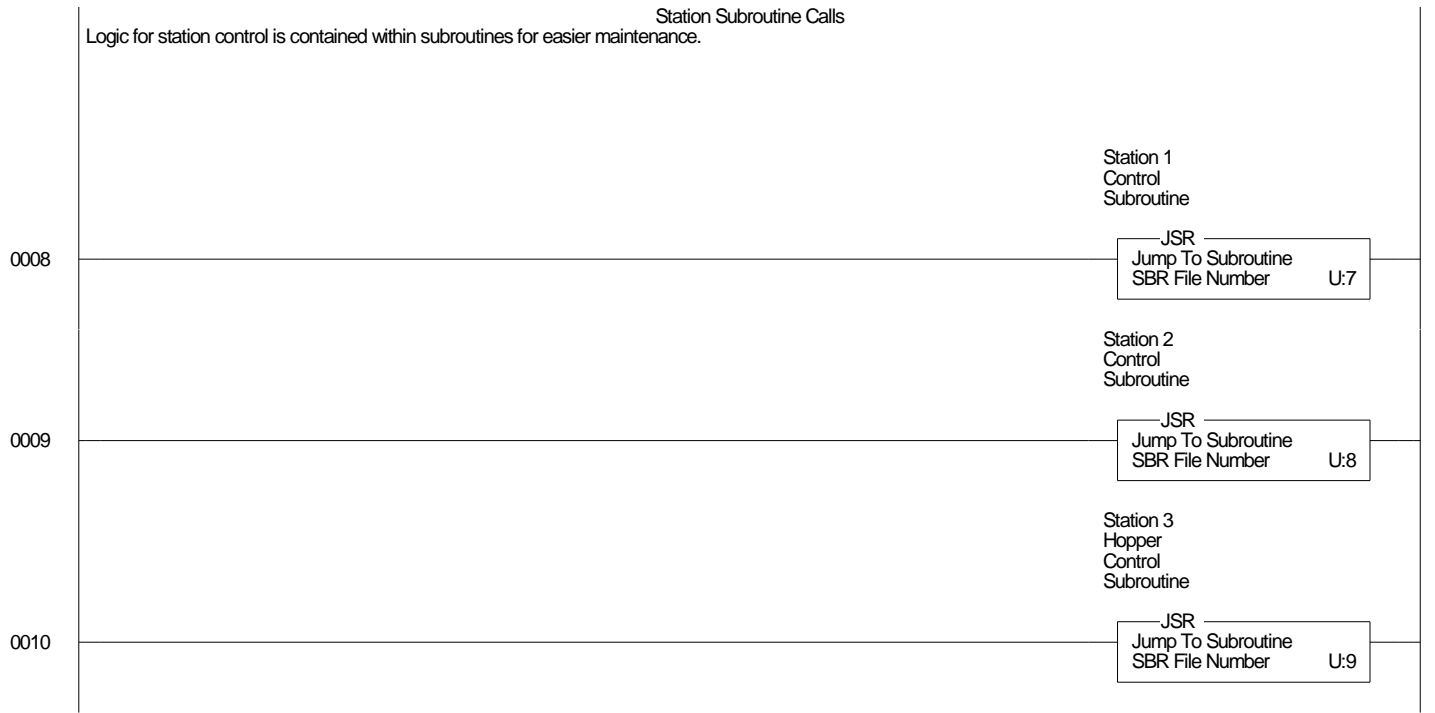

If the counter ever goes to some wierd value, then plonk it back down to station 1 by resetting the counter.
 Reset the station count when the last stage has completed, and on first PLC scan.

This is the core rung of the station selection logic. The count increments cyclically and pauses when it encounters a station with a fill in progress. When the fill completes cycling resumes.
 1= Station 1
 2= Station 2
 3= Station 3
 Insert additional 'in progress' contacts to add more stations.

Vac Pump Control

This timer allows the vac pump to run for the setpoint time after the last station has called for material to minimize the number of times the pump is cycled on, and improve system speed. Set to a low value or eliminate when using soft starters.

When no stations have called to be filled turn on this bit. It is used to control vacuum loader operation.

Unlatch the call for vac upon initialization, and when no station is calling for material.

After dump initialize completes on startup, the vac pump run status is controlled by the stations as they call for fill. If the motor auxiliary does not close the circuit within T4:7 after a call for motor start then a fault will occur.

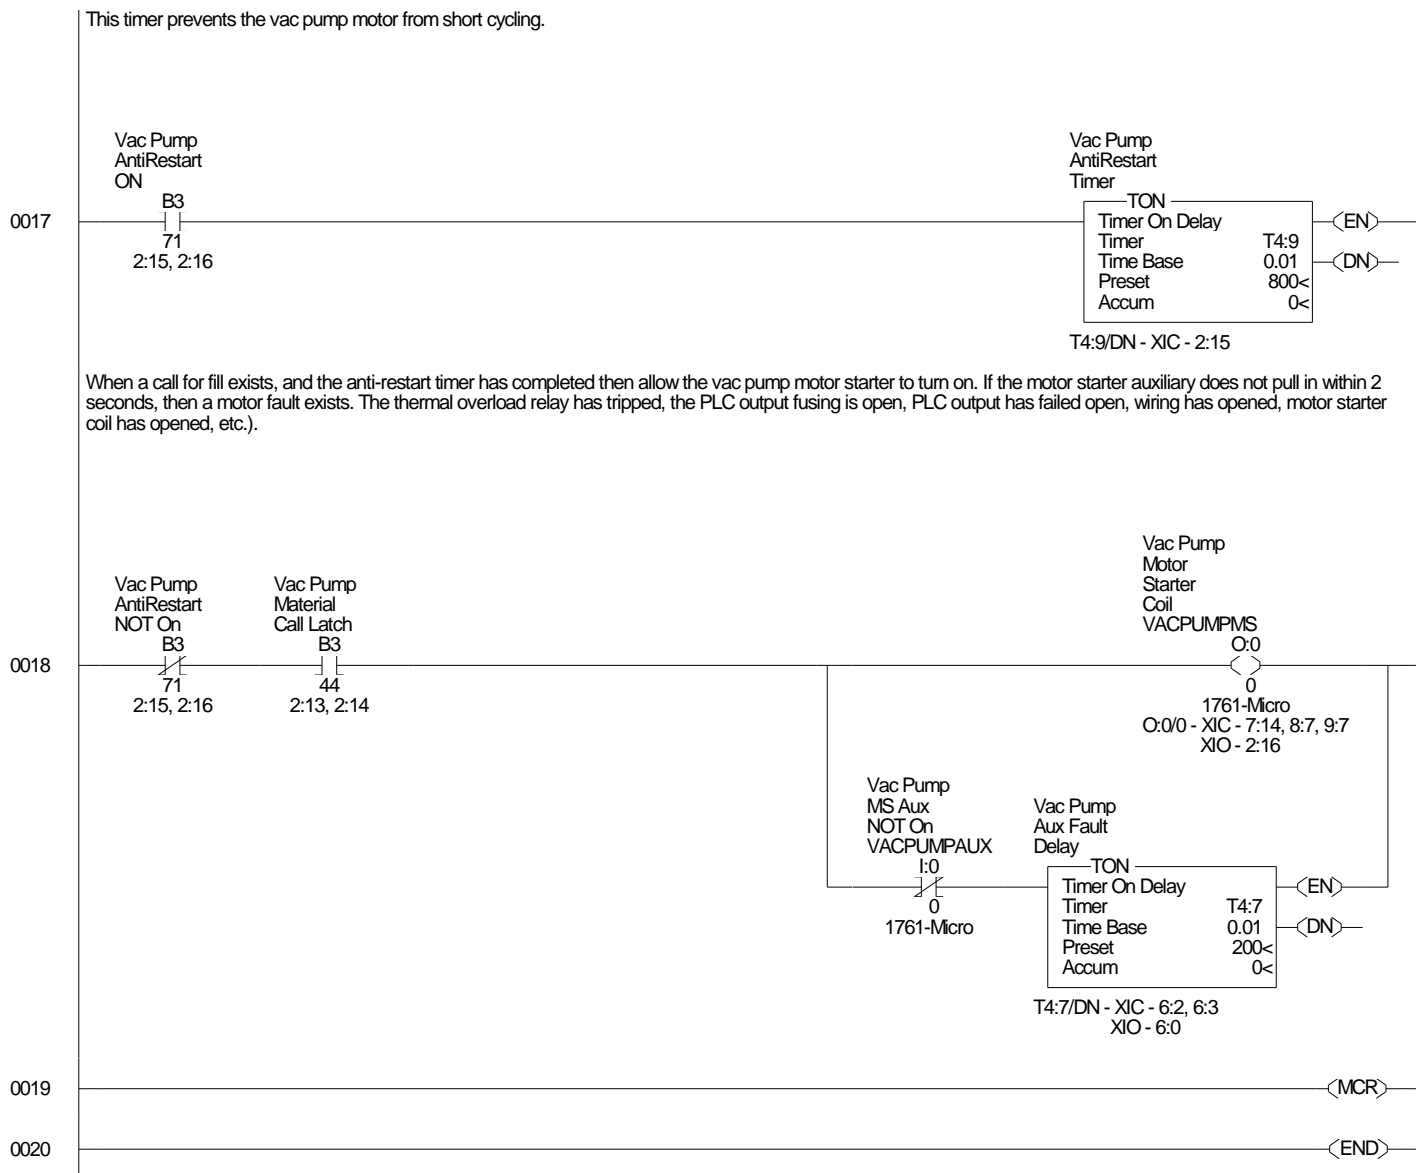

After the anti-restart timer finishes, and the DN (done) bit is set the next call for material will unlatch the anti-restart bit, and allow the vac pump to turn on again.

The moment the vac pump turns off, and there isn't a call for fill then one shot on this latch relay, which is then timed out for the setpoint in the 'Vac Pump Antirestart' timer. This prevents the pump from short cycling.

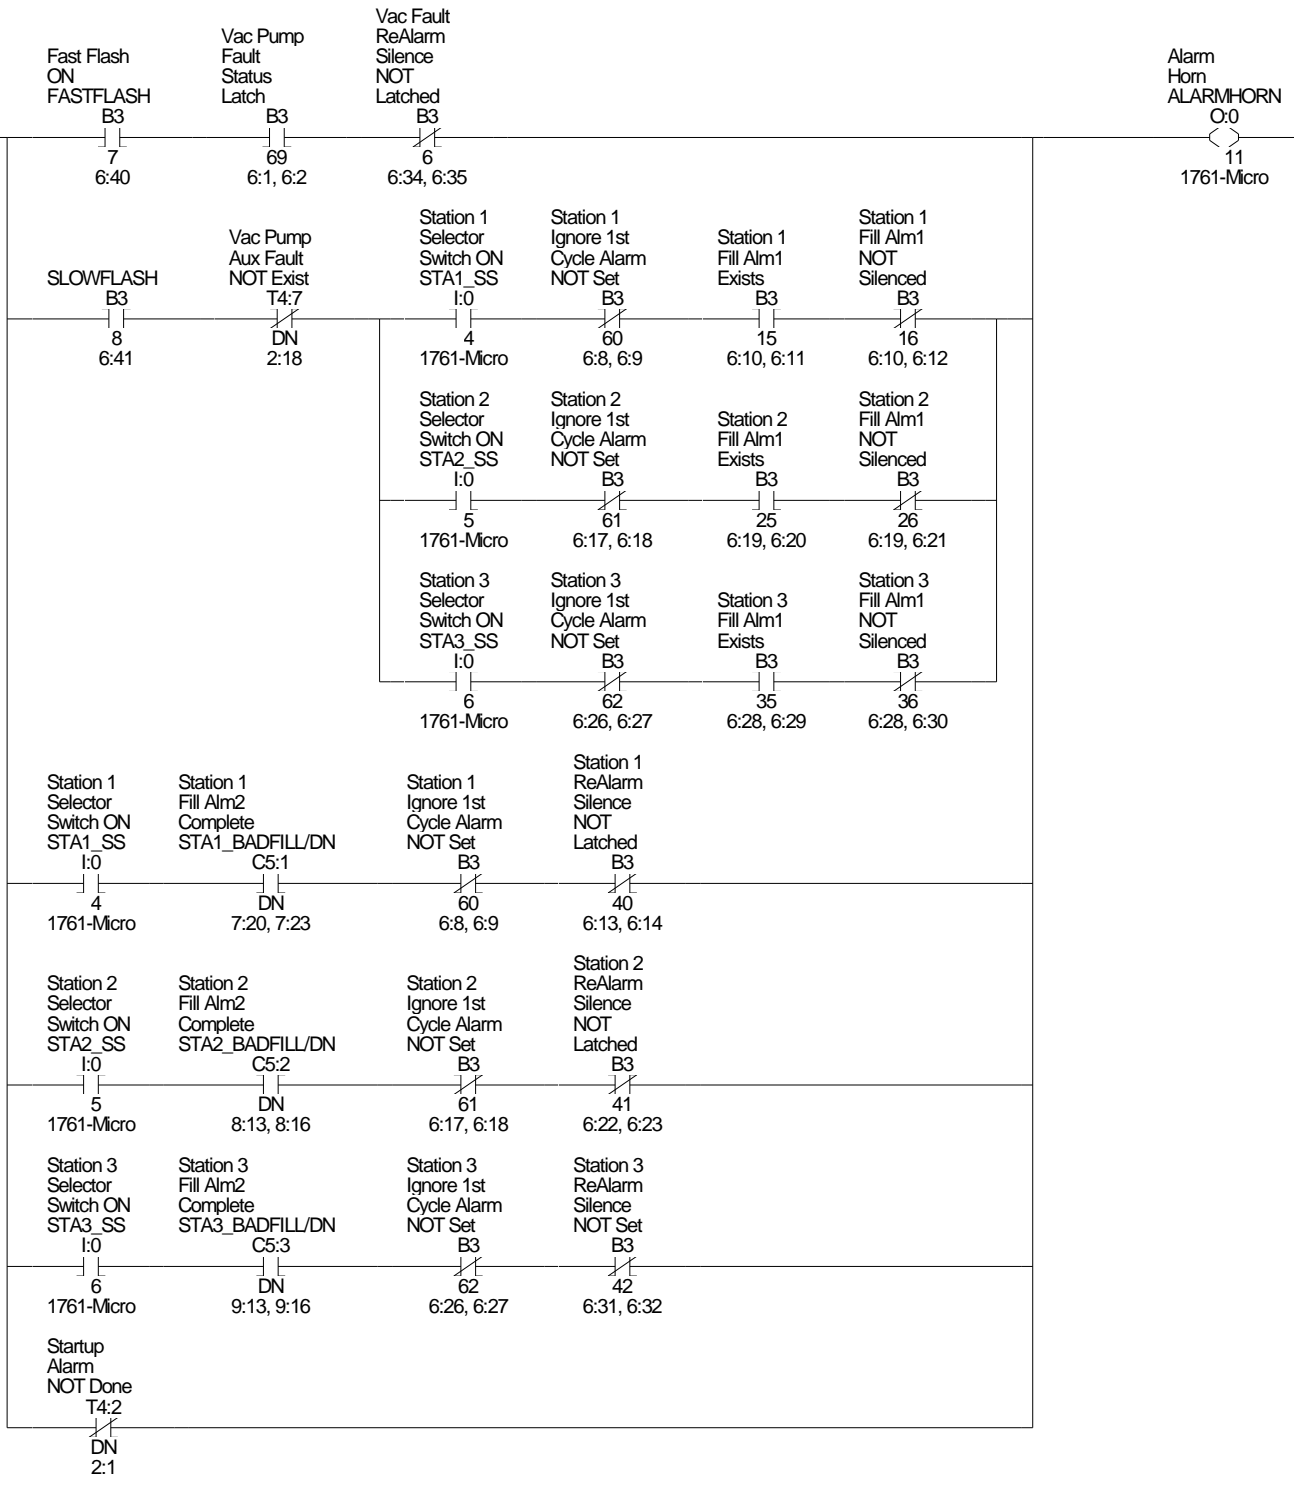

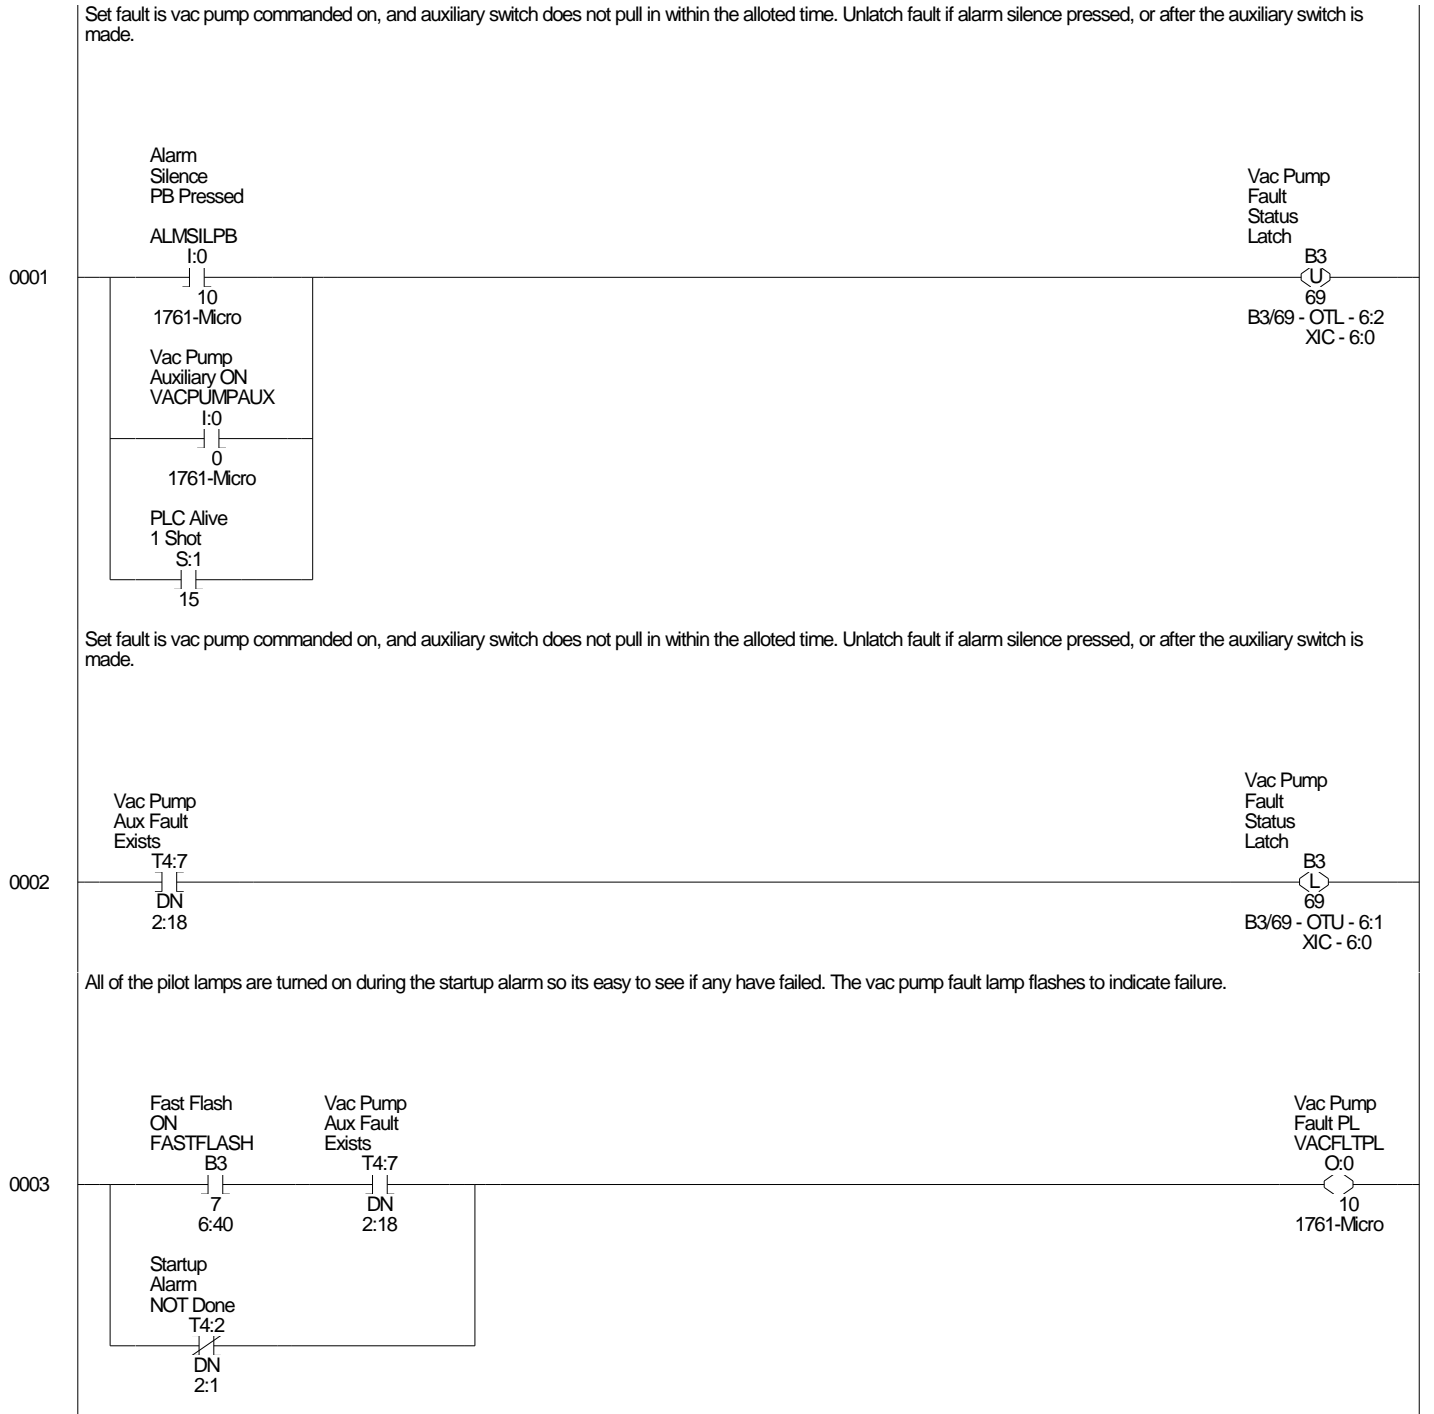

Alarm Horn

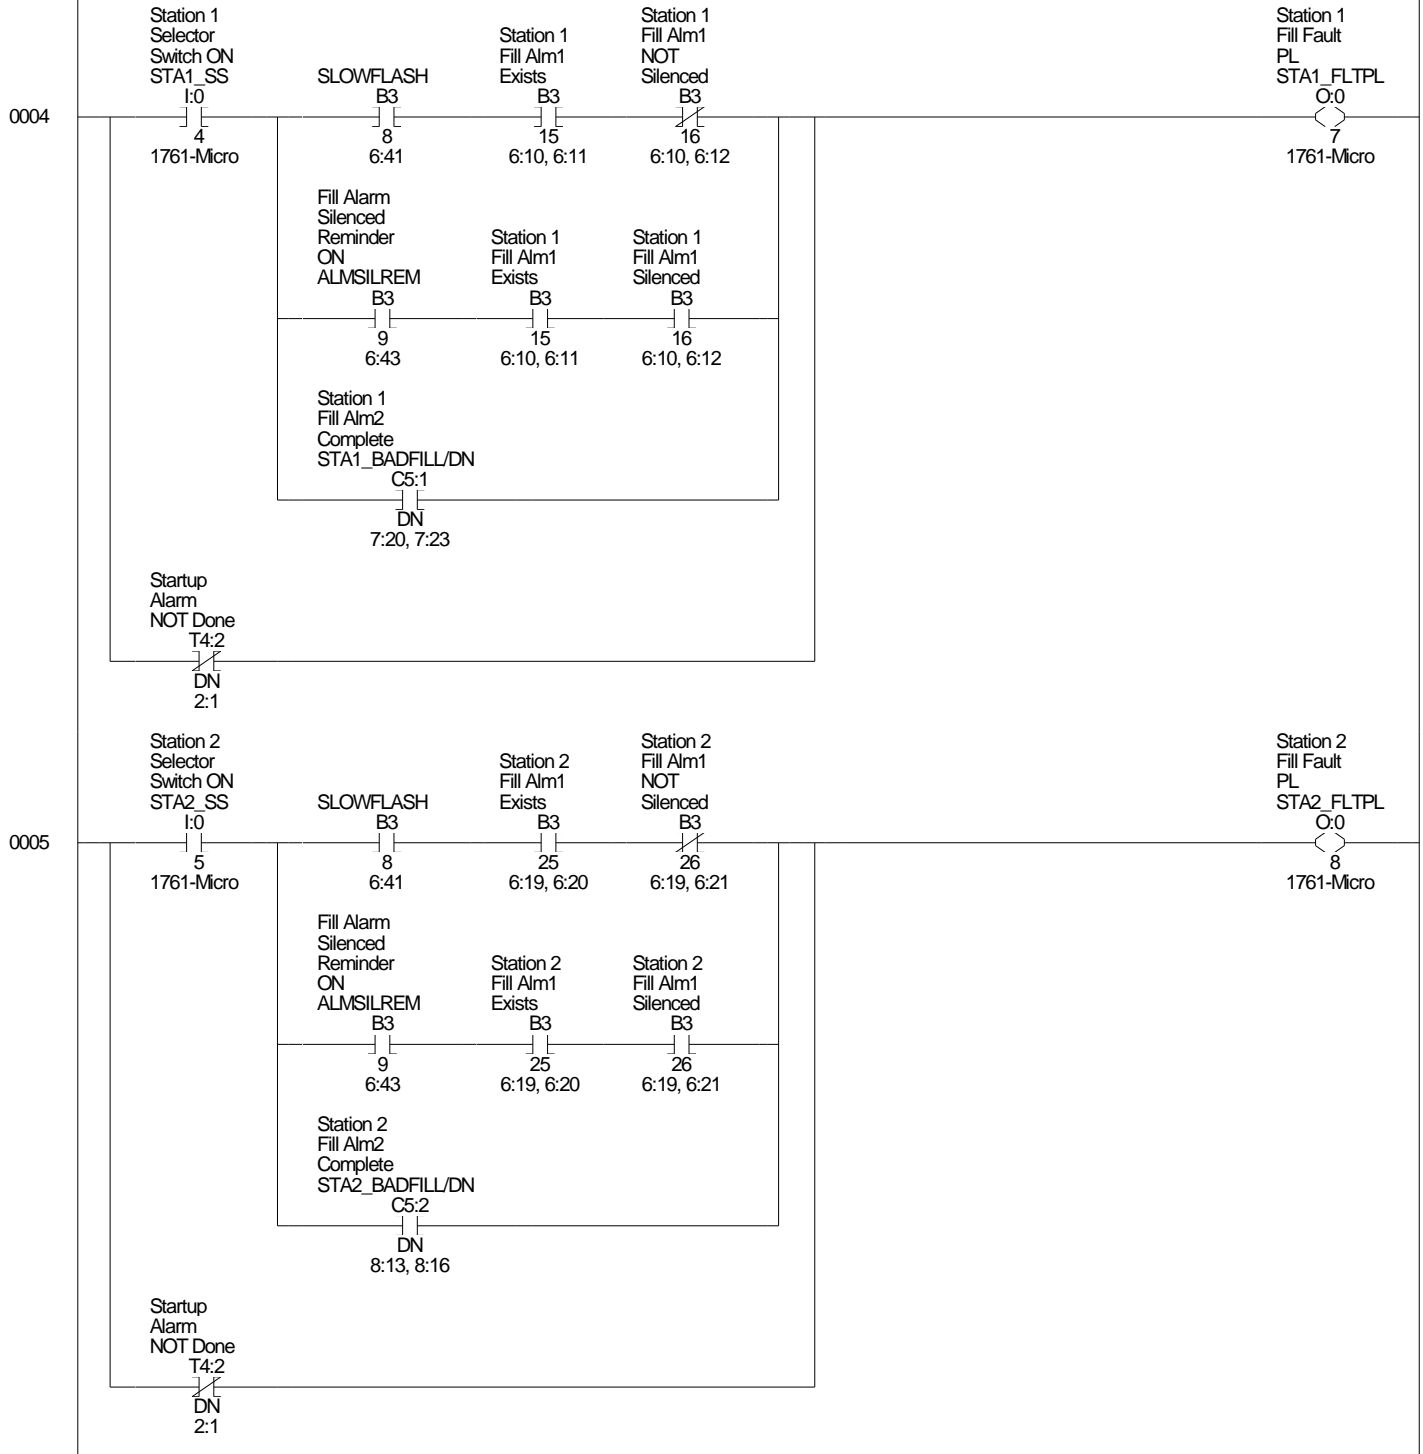

This is the alarm horn logic featuring several rate and priority levels.
 Status pilot lamps are turned on during initialization to show their operational status (functioning or burned-out).

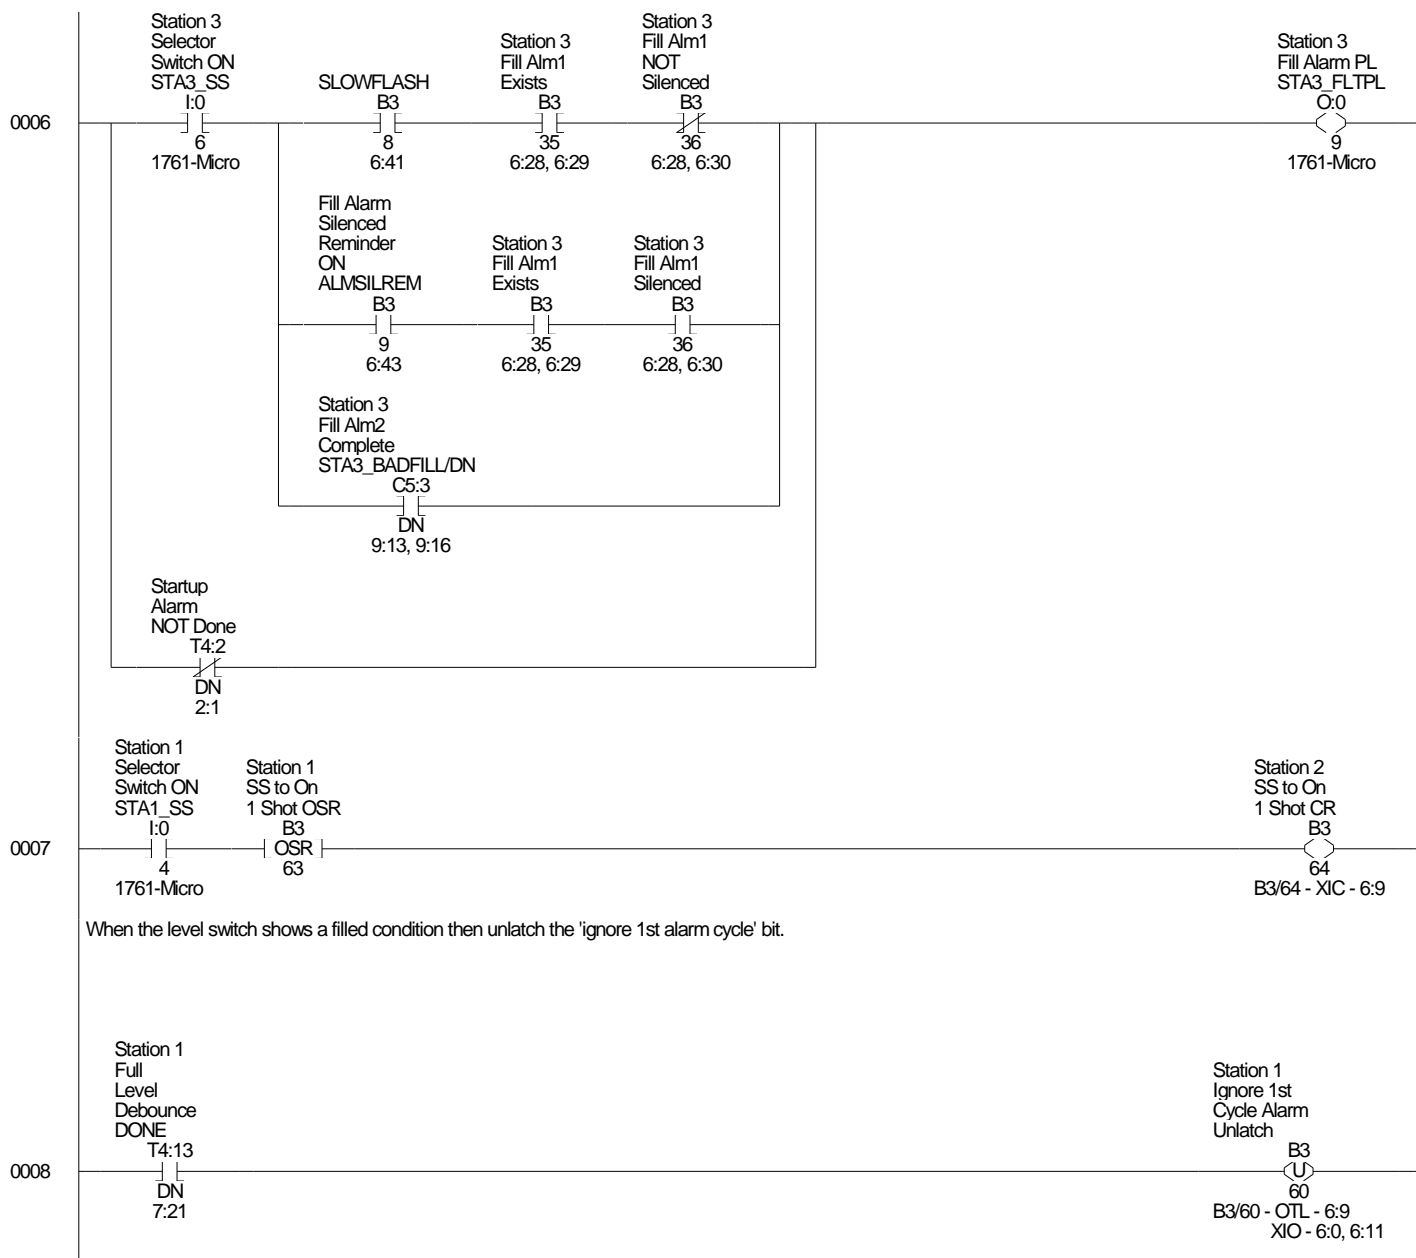

0000

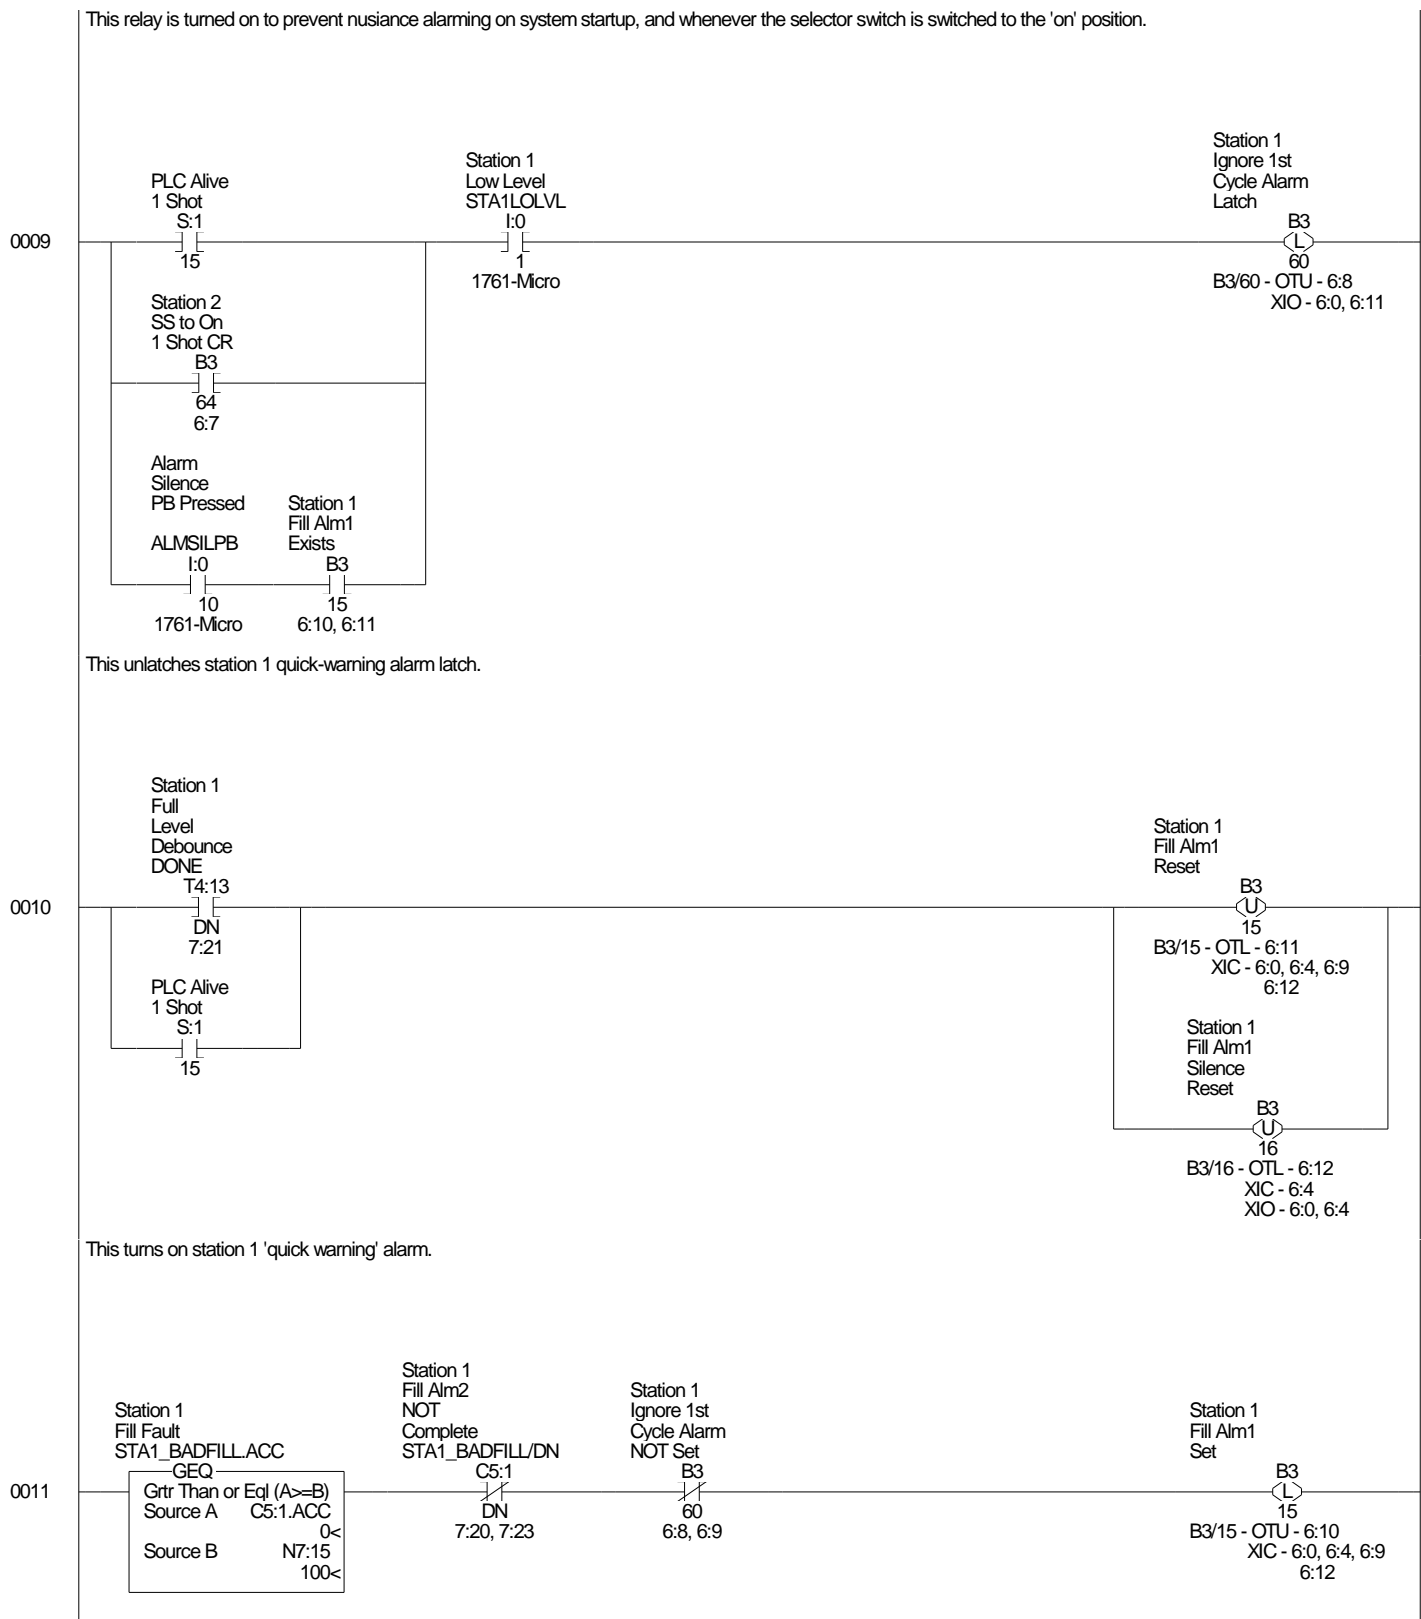

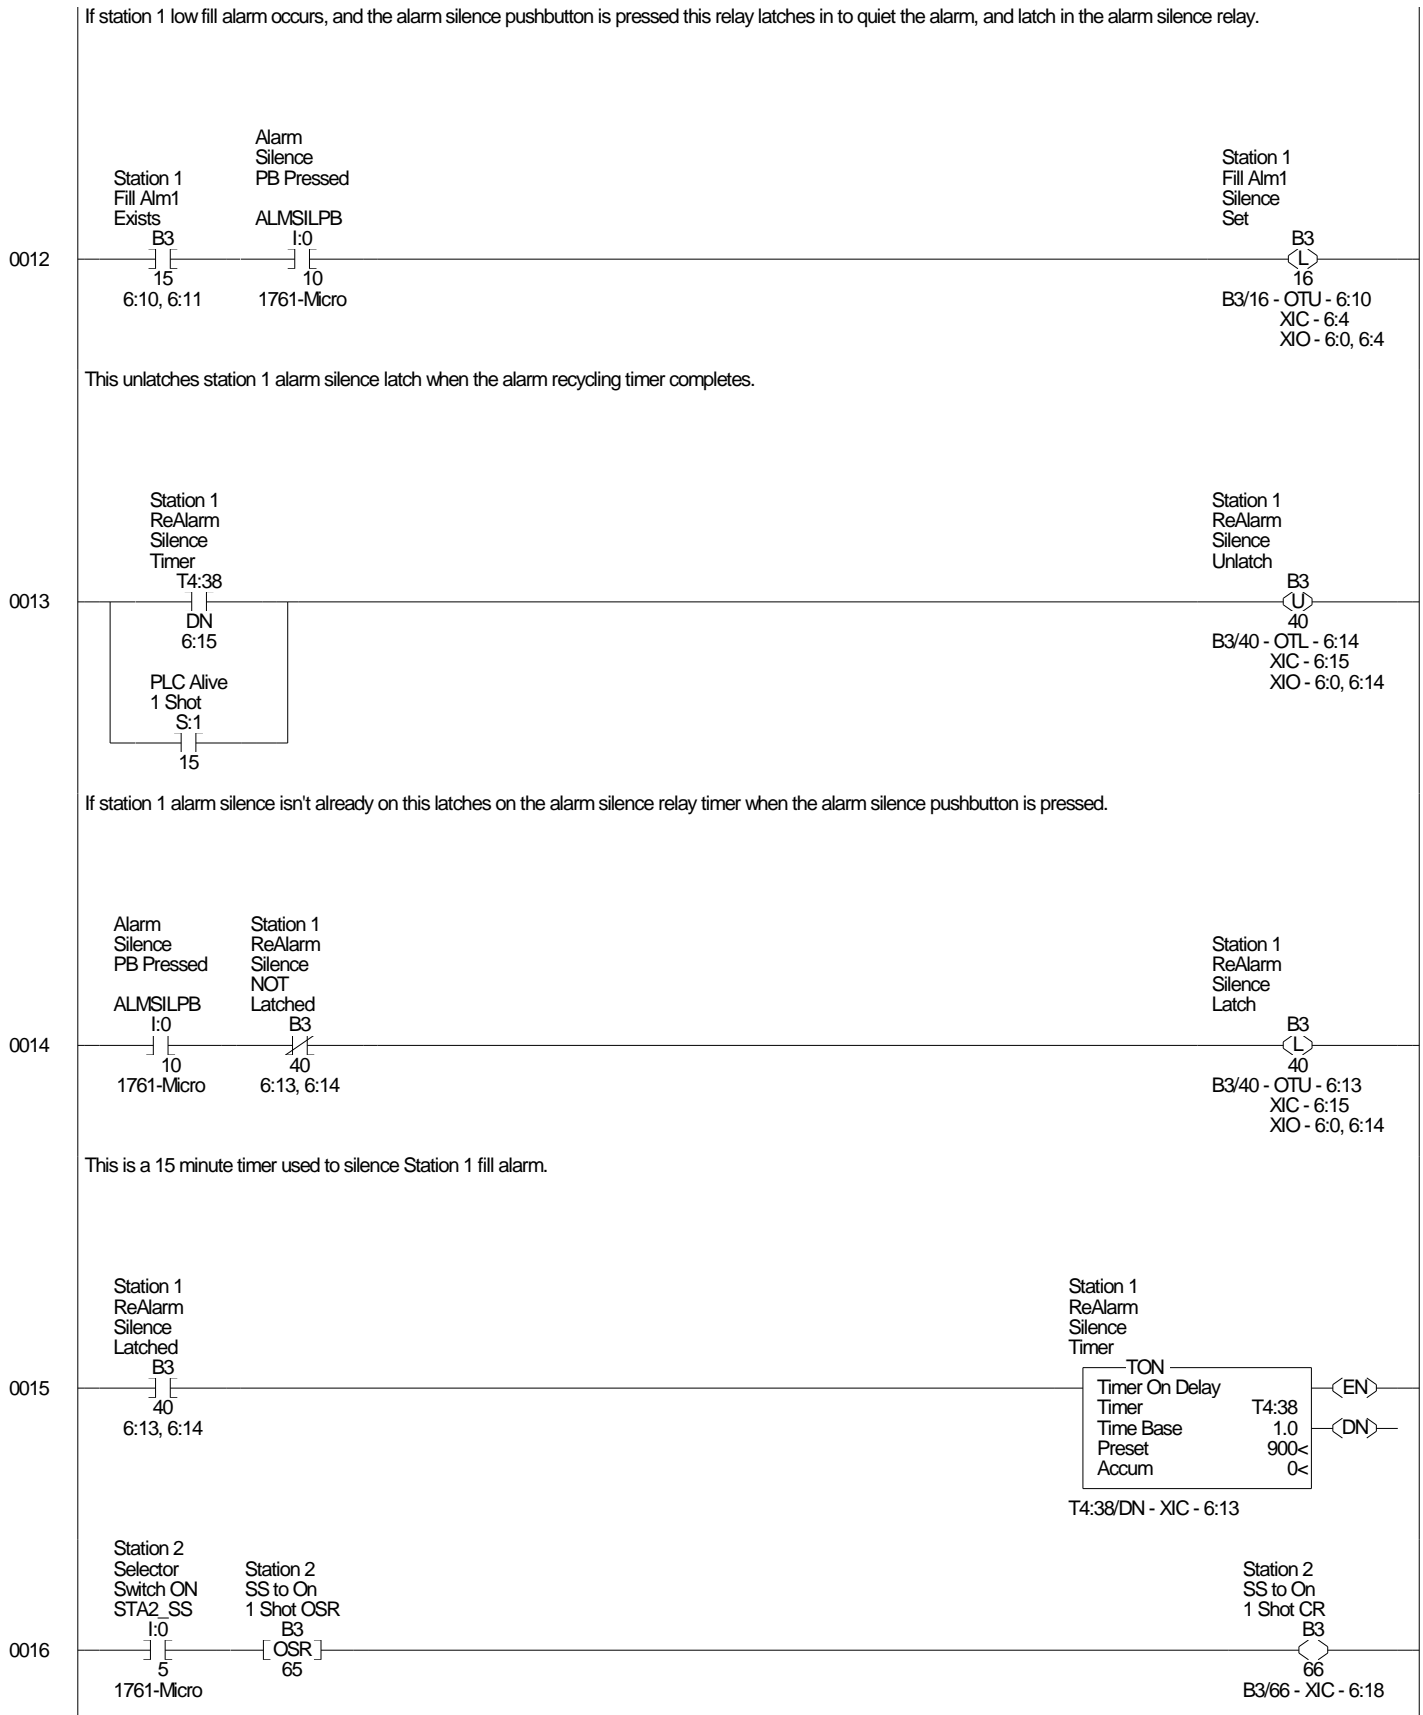

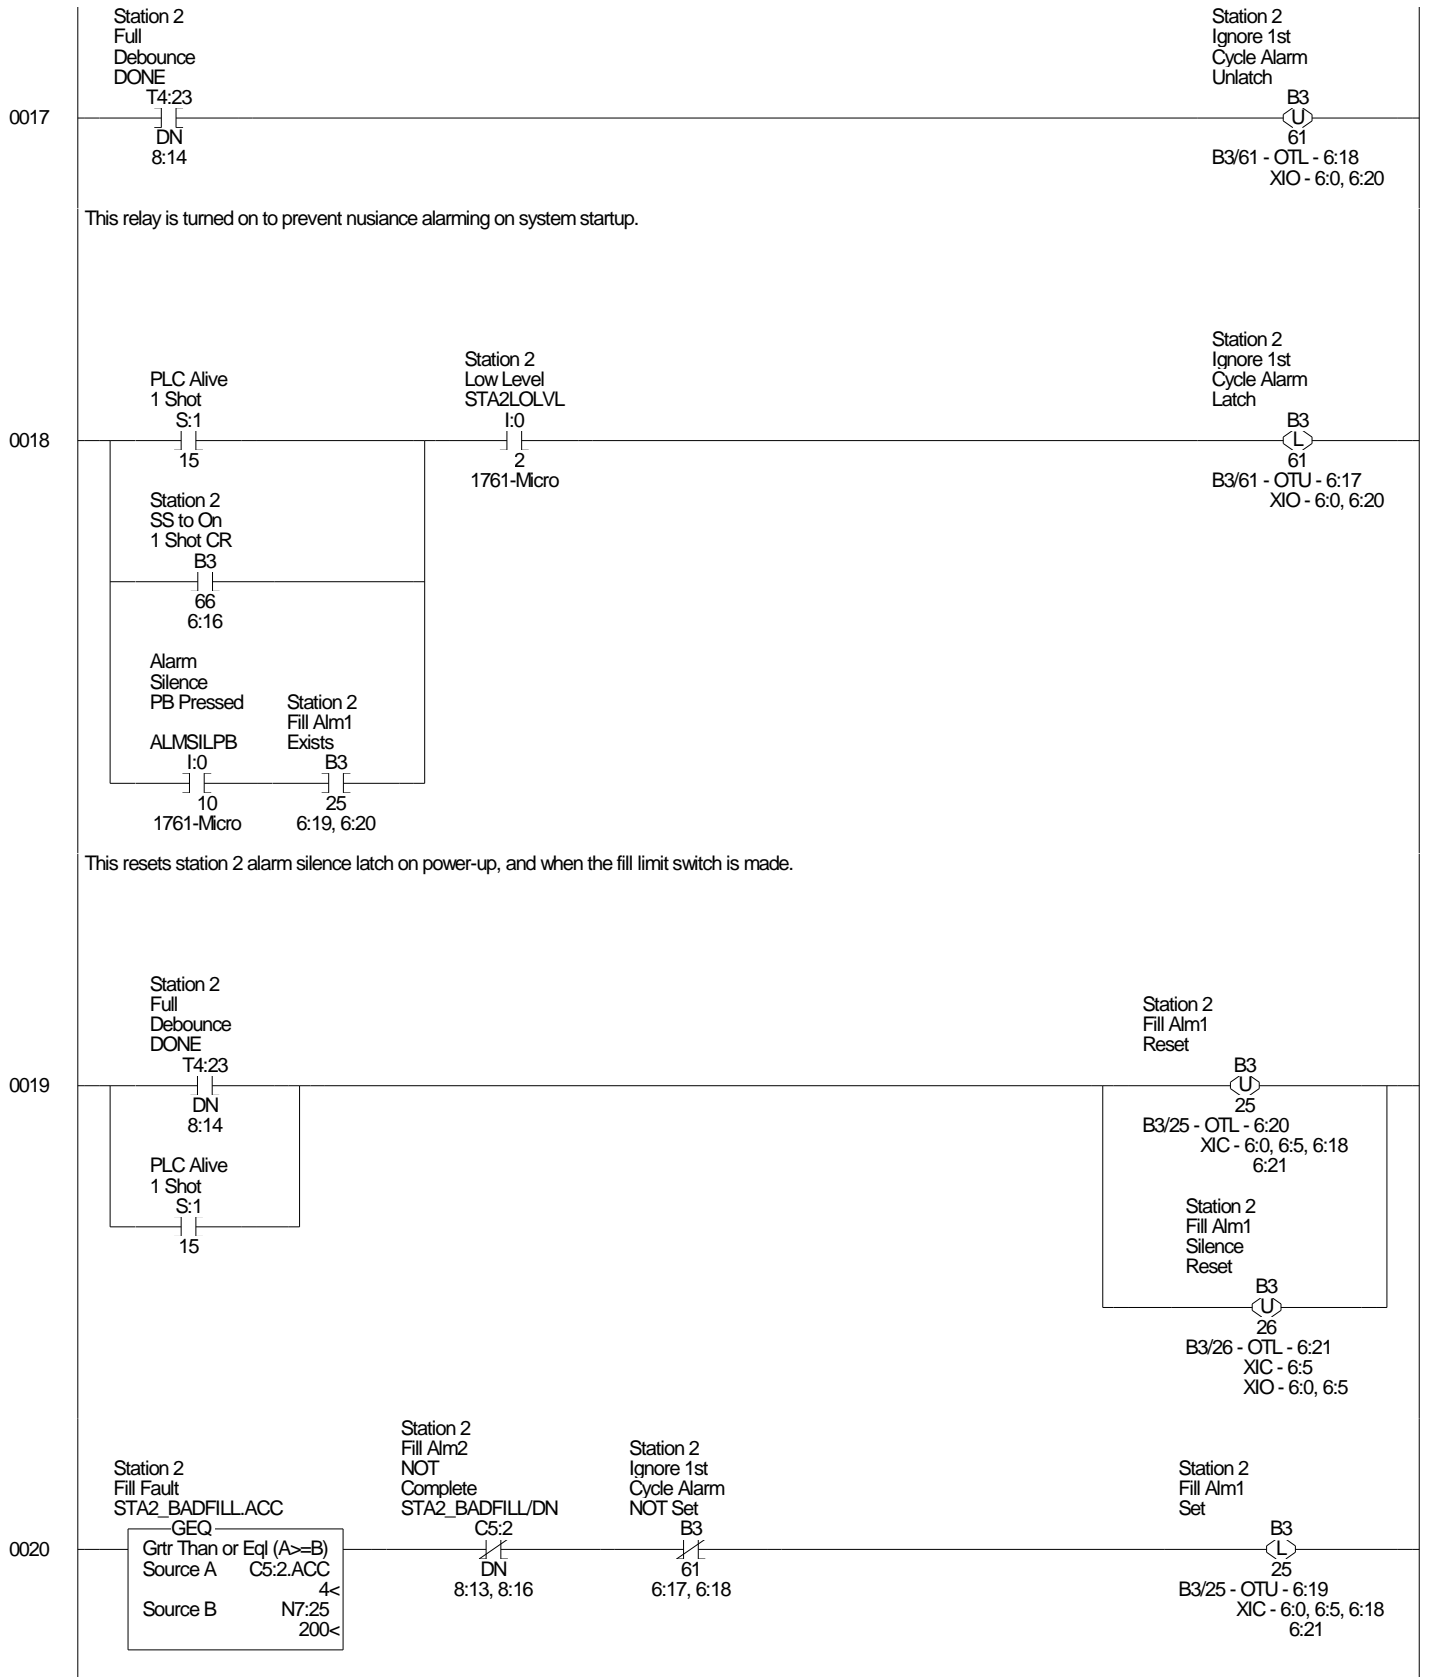

Slow flash for an early warning of poor filling performance, and turn on 100% for load failure.

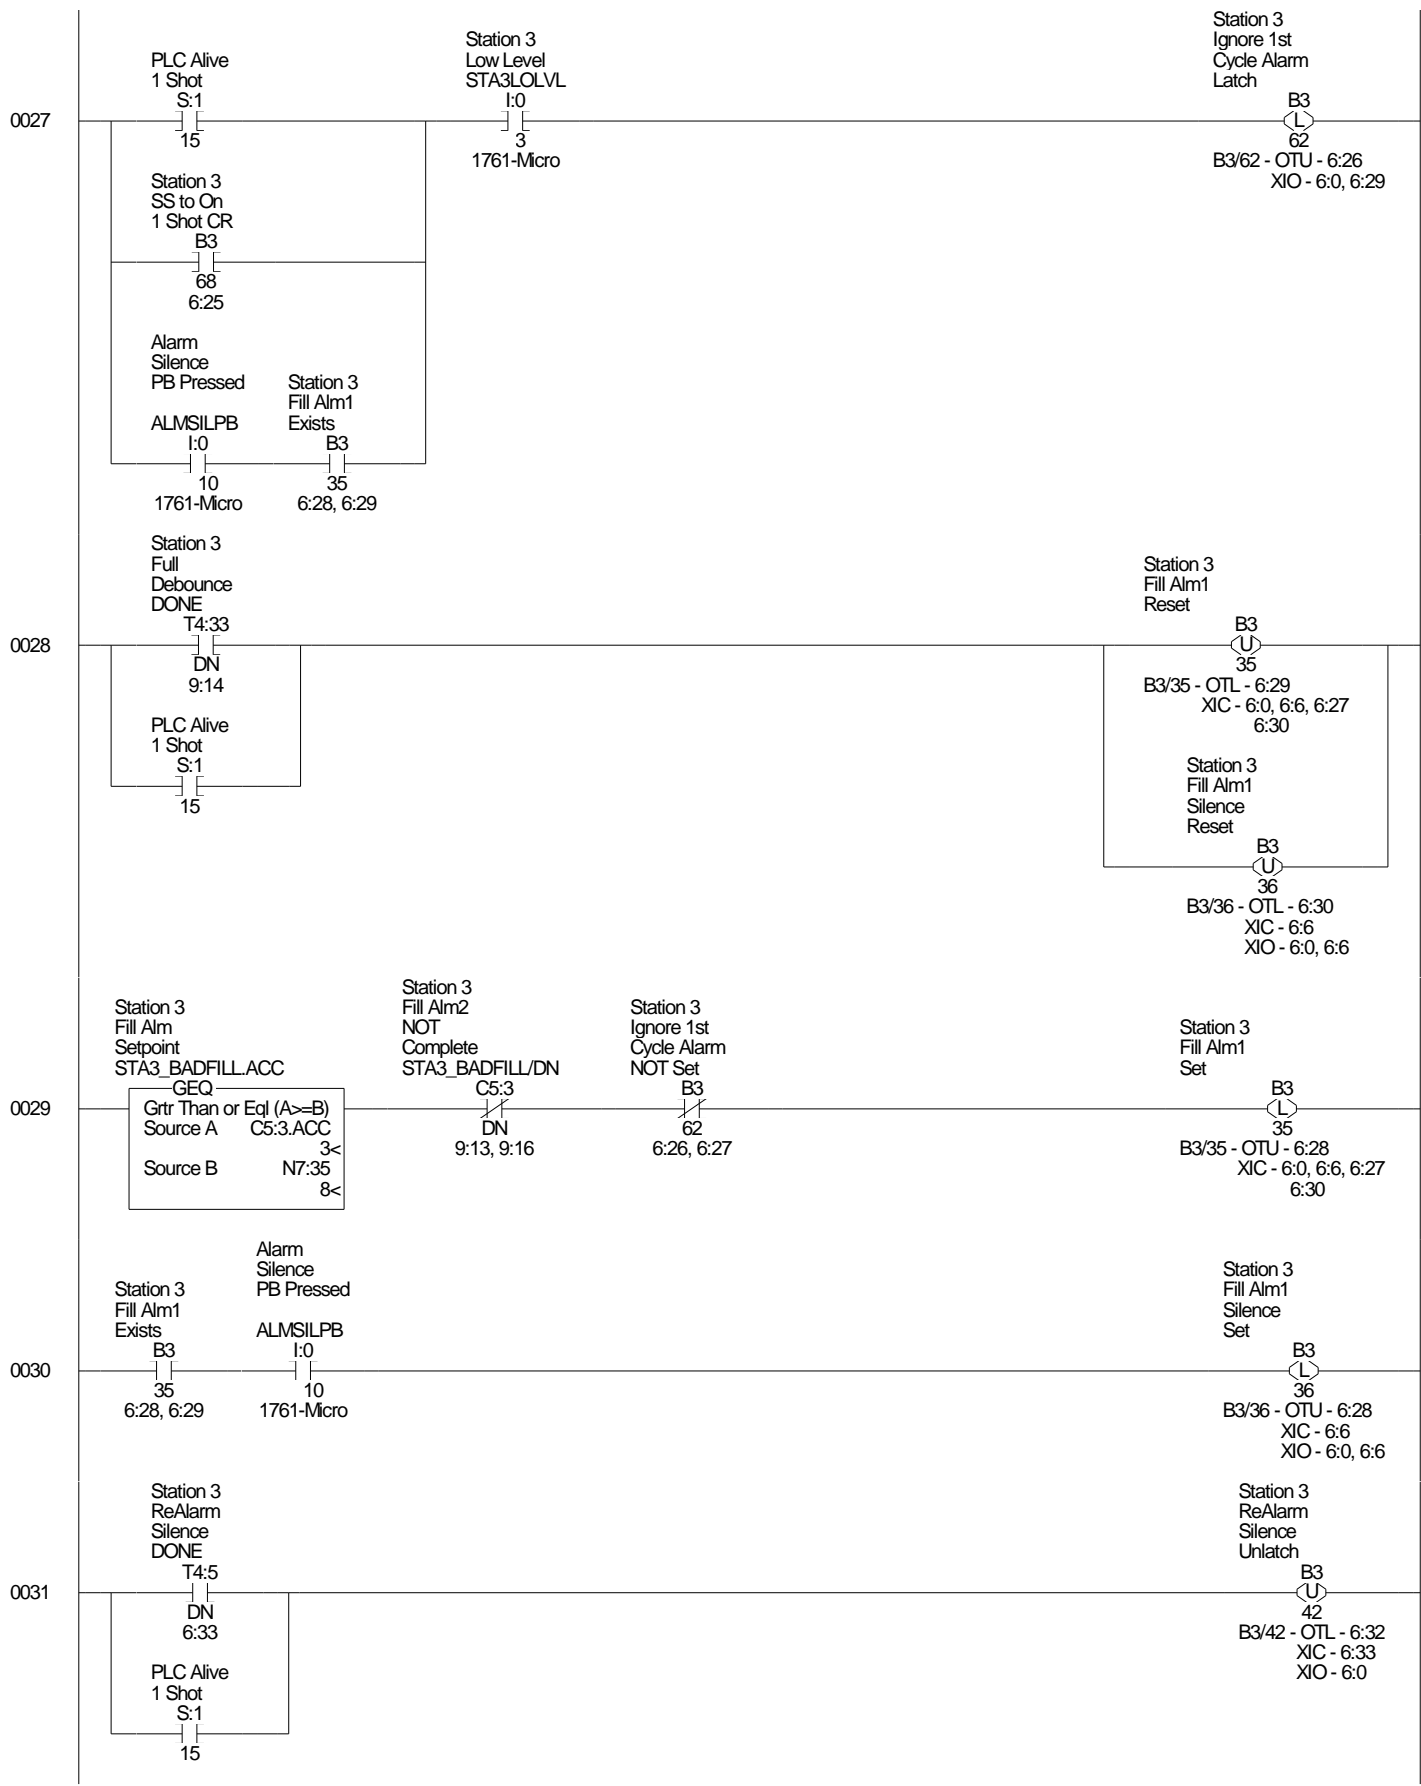

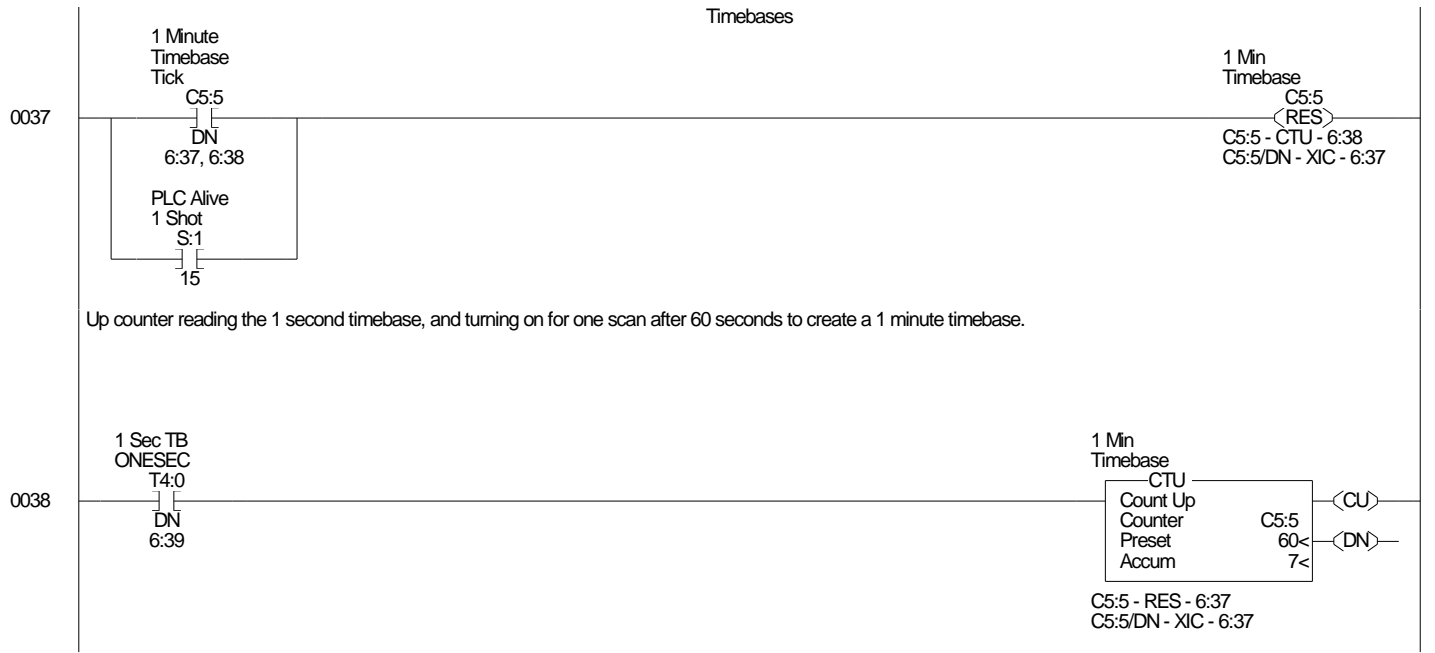

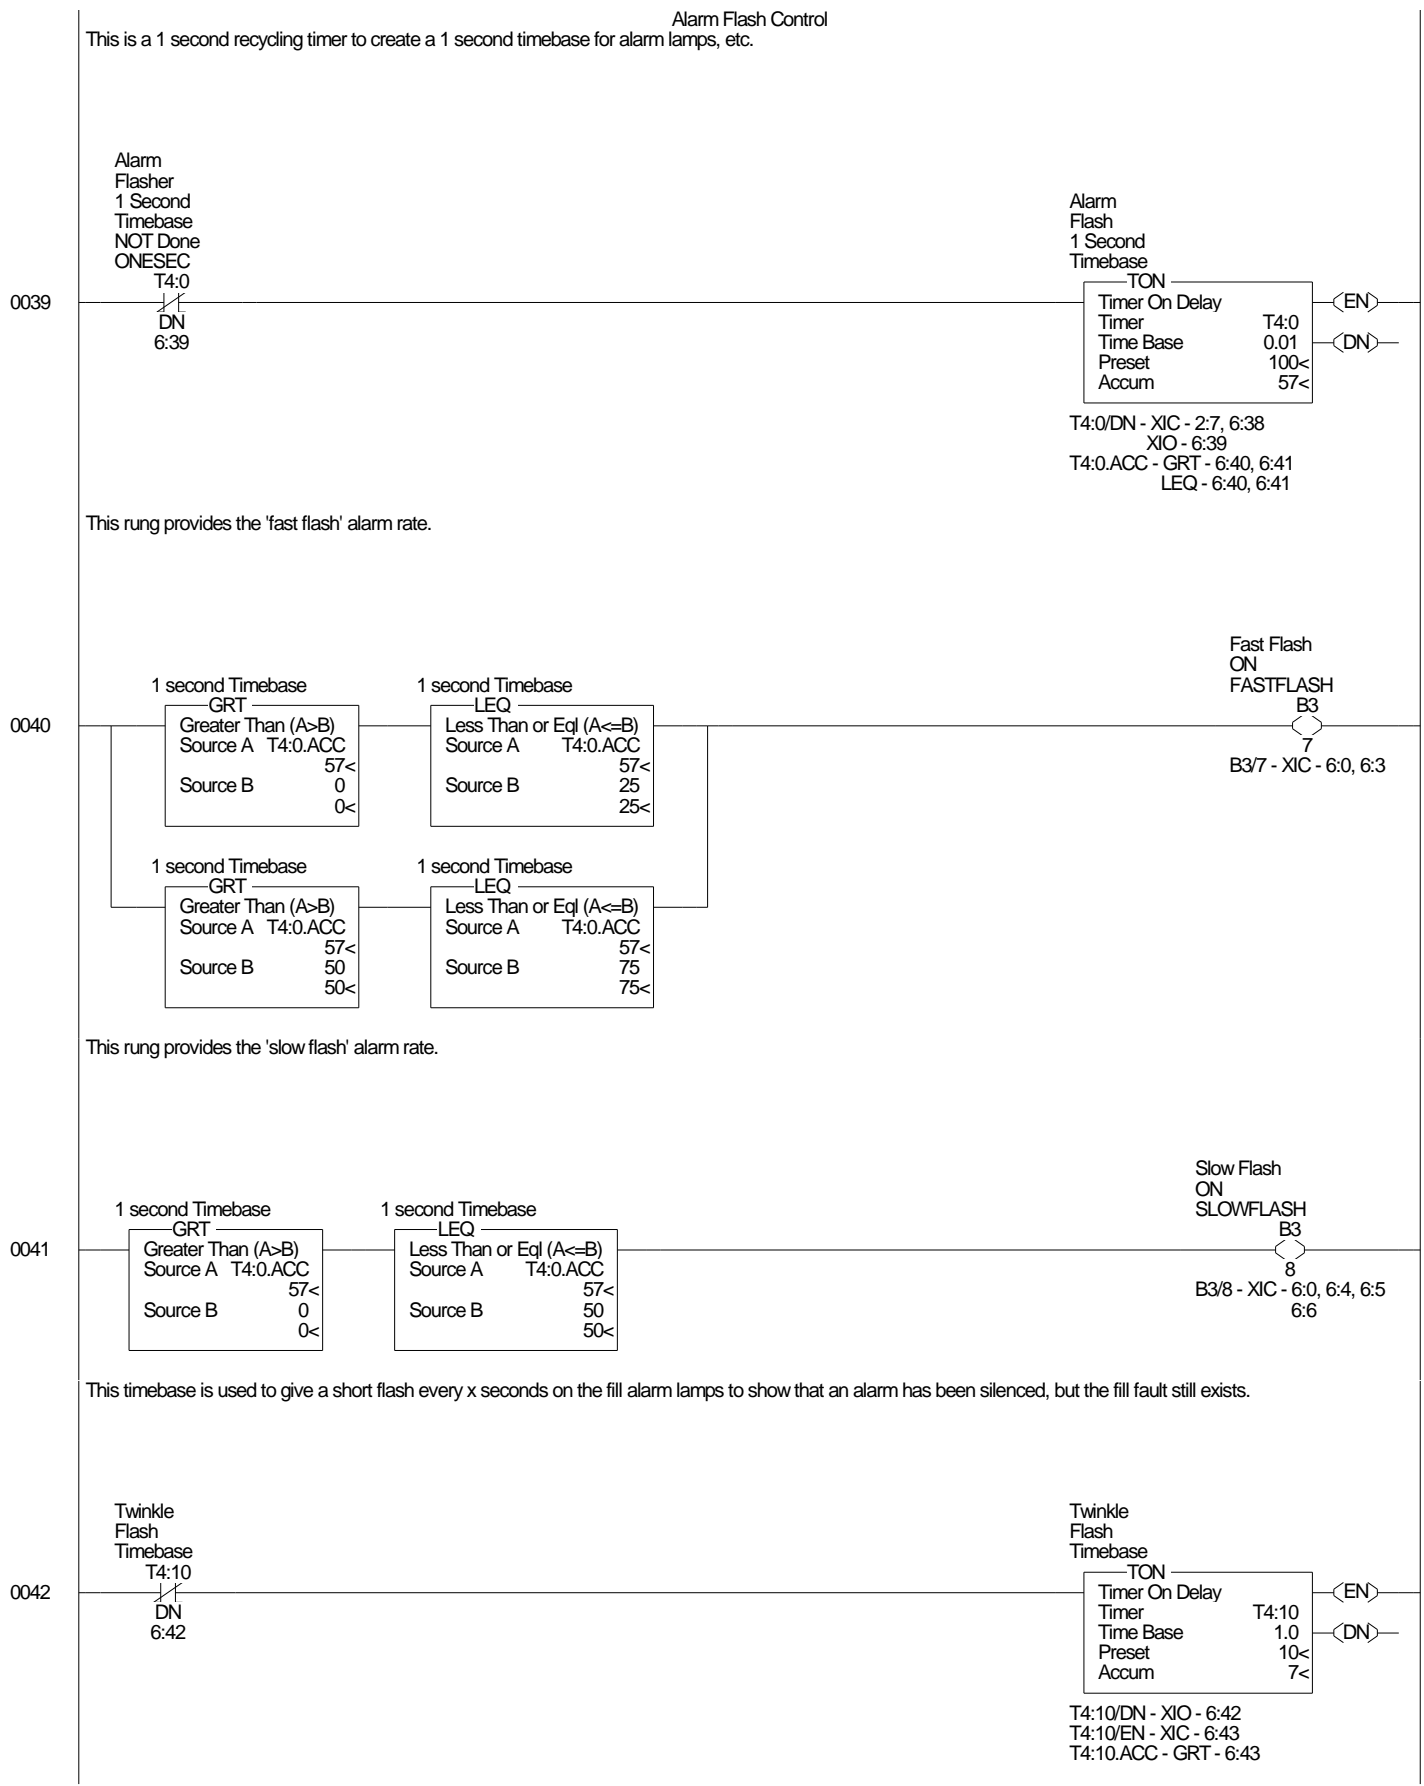

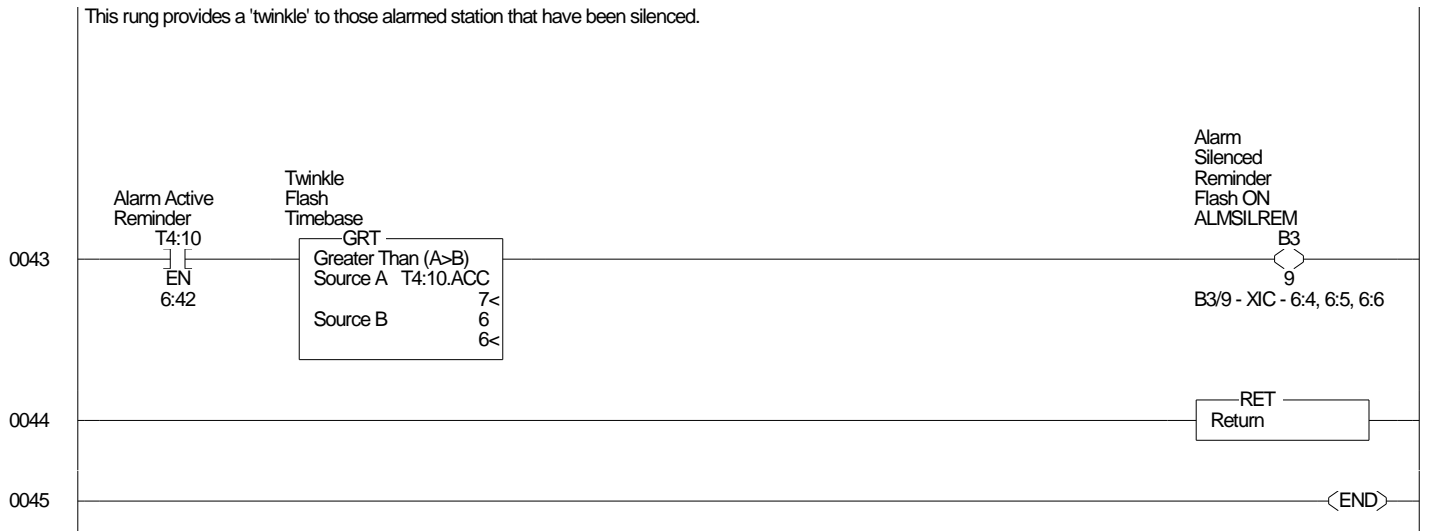

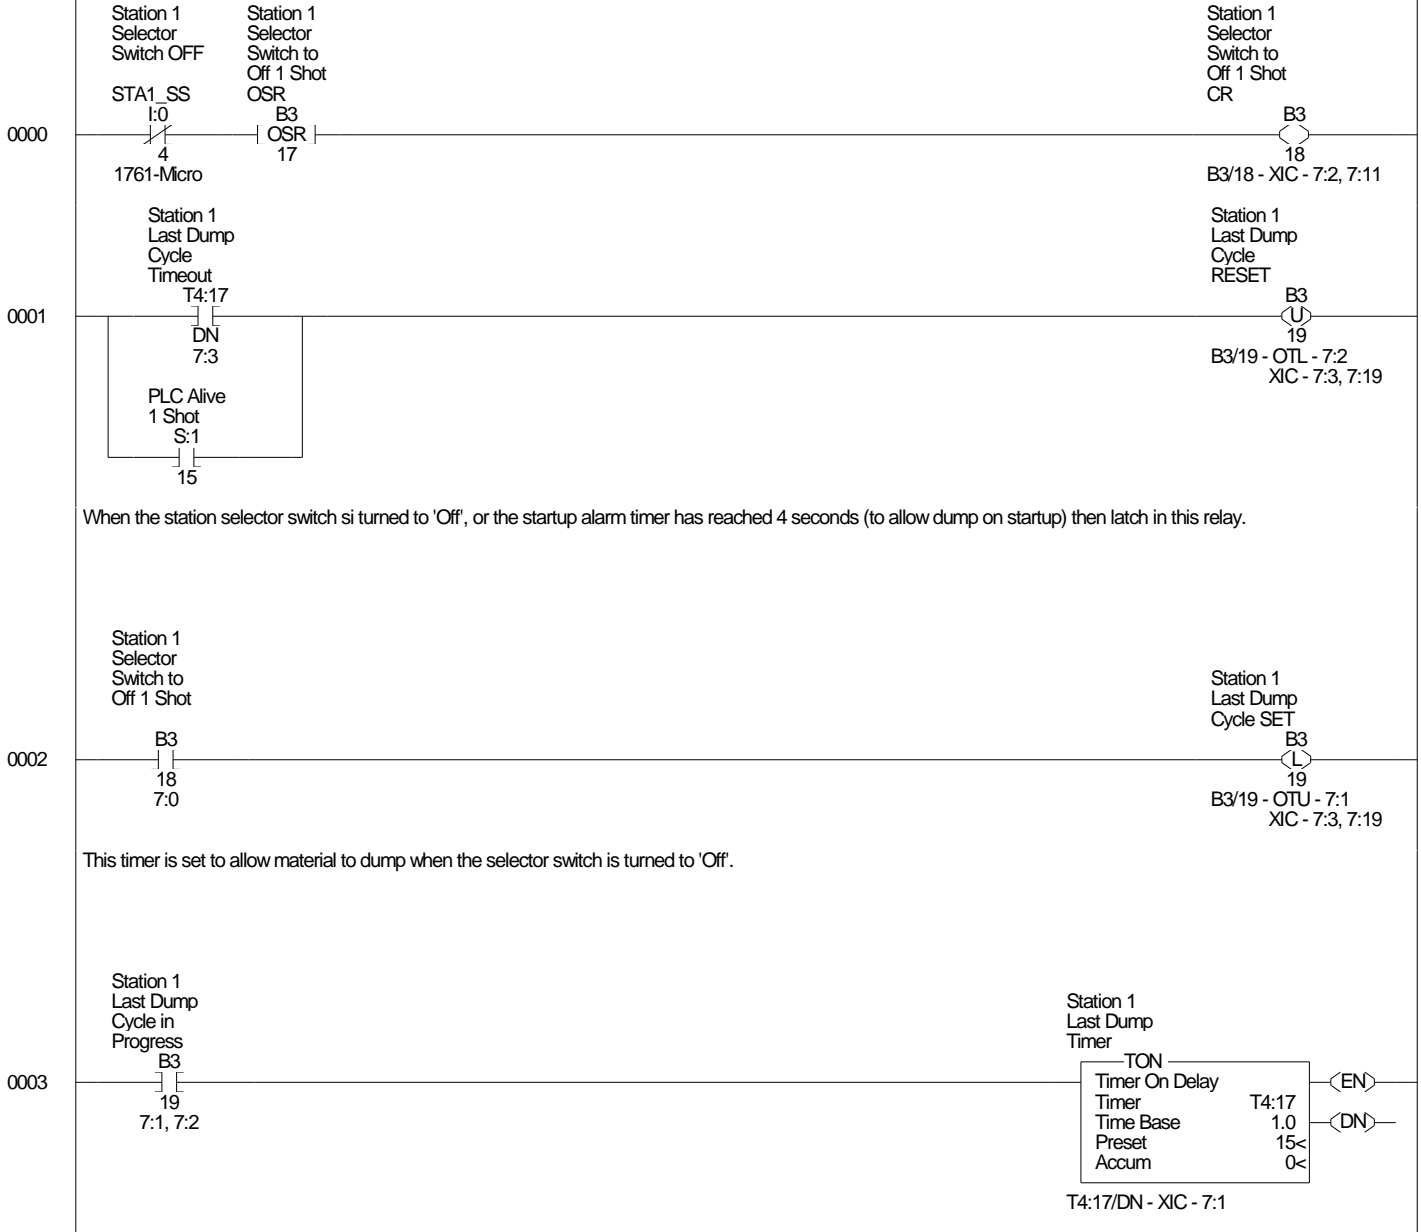

Station 1 Control Subroutine

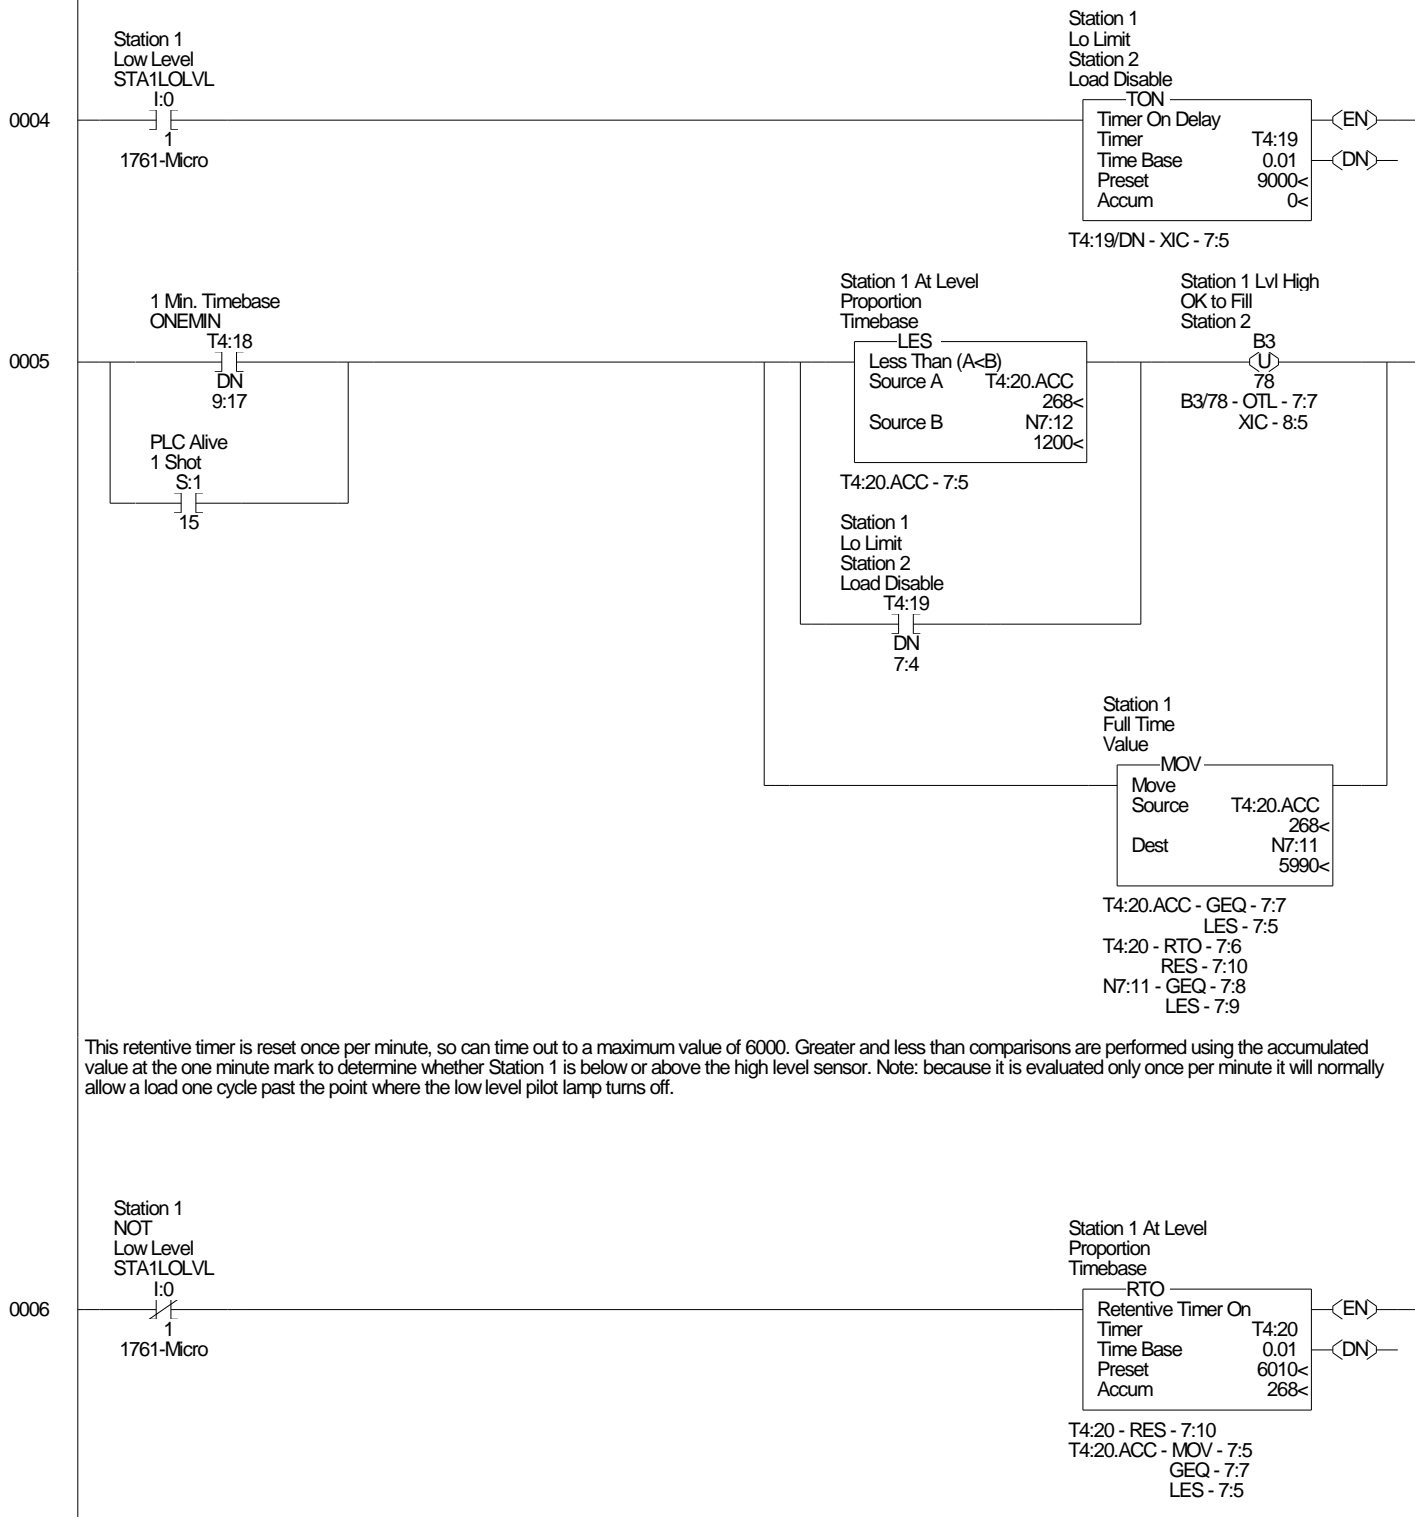

This uses the same control logic as the other two, but with a twist - the system this was originally written for had an agitated hopper, and the level switch operation was highly variable. This station shows an example of crude proportioning control using a retentive timer to decouple the agitation effect from level measurement.

When the station selector switch si turned to 'Off', or the startup alarm timer has reached 4 seconds (to allow dump on startup) then latch in this relay.

This timer is set to allow material to dump when the selector switch is turned to 'Off'.

Station 1 - Allow Dryer Load Level Determination
 When a low level is sensed for greater than the setpoint (default of 90 seconds) dryer loading is unconditionally disabled until a full condition is again sensed.

This retentive timer is reset once per minute, so can time out to a maximum value of 6000. Greater and less than comparisons are performed using the accumulated value at the one minute mark to determine whether Station 1 is below or above the high level sensor. Note: because it is evaluated only once per minute it will normally allow a load one cycle past the point where the low level pilot lamp turns off.

These rungs are a crude proportioning device to show station 1 fill level. The high level sensor is fed into a retentive timer, and the accumulated time is evaluated every minute. If the full time is more than 50% then station 1 is considered full, and if less than 30% considered empty. The proportioning values aren't programic, and can be changed by altering the N7 registers to other values.

If station 1 level is high for less than half the time (3000 of 6000 - 30 in 60 seconds) then consider it low.

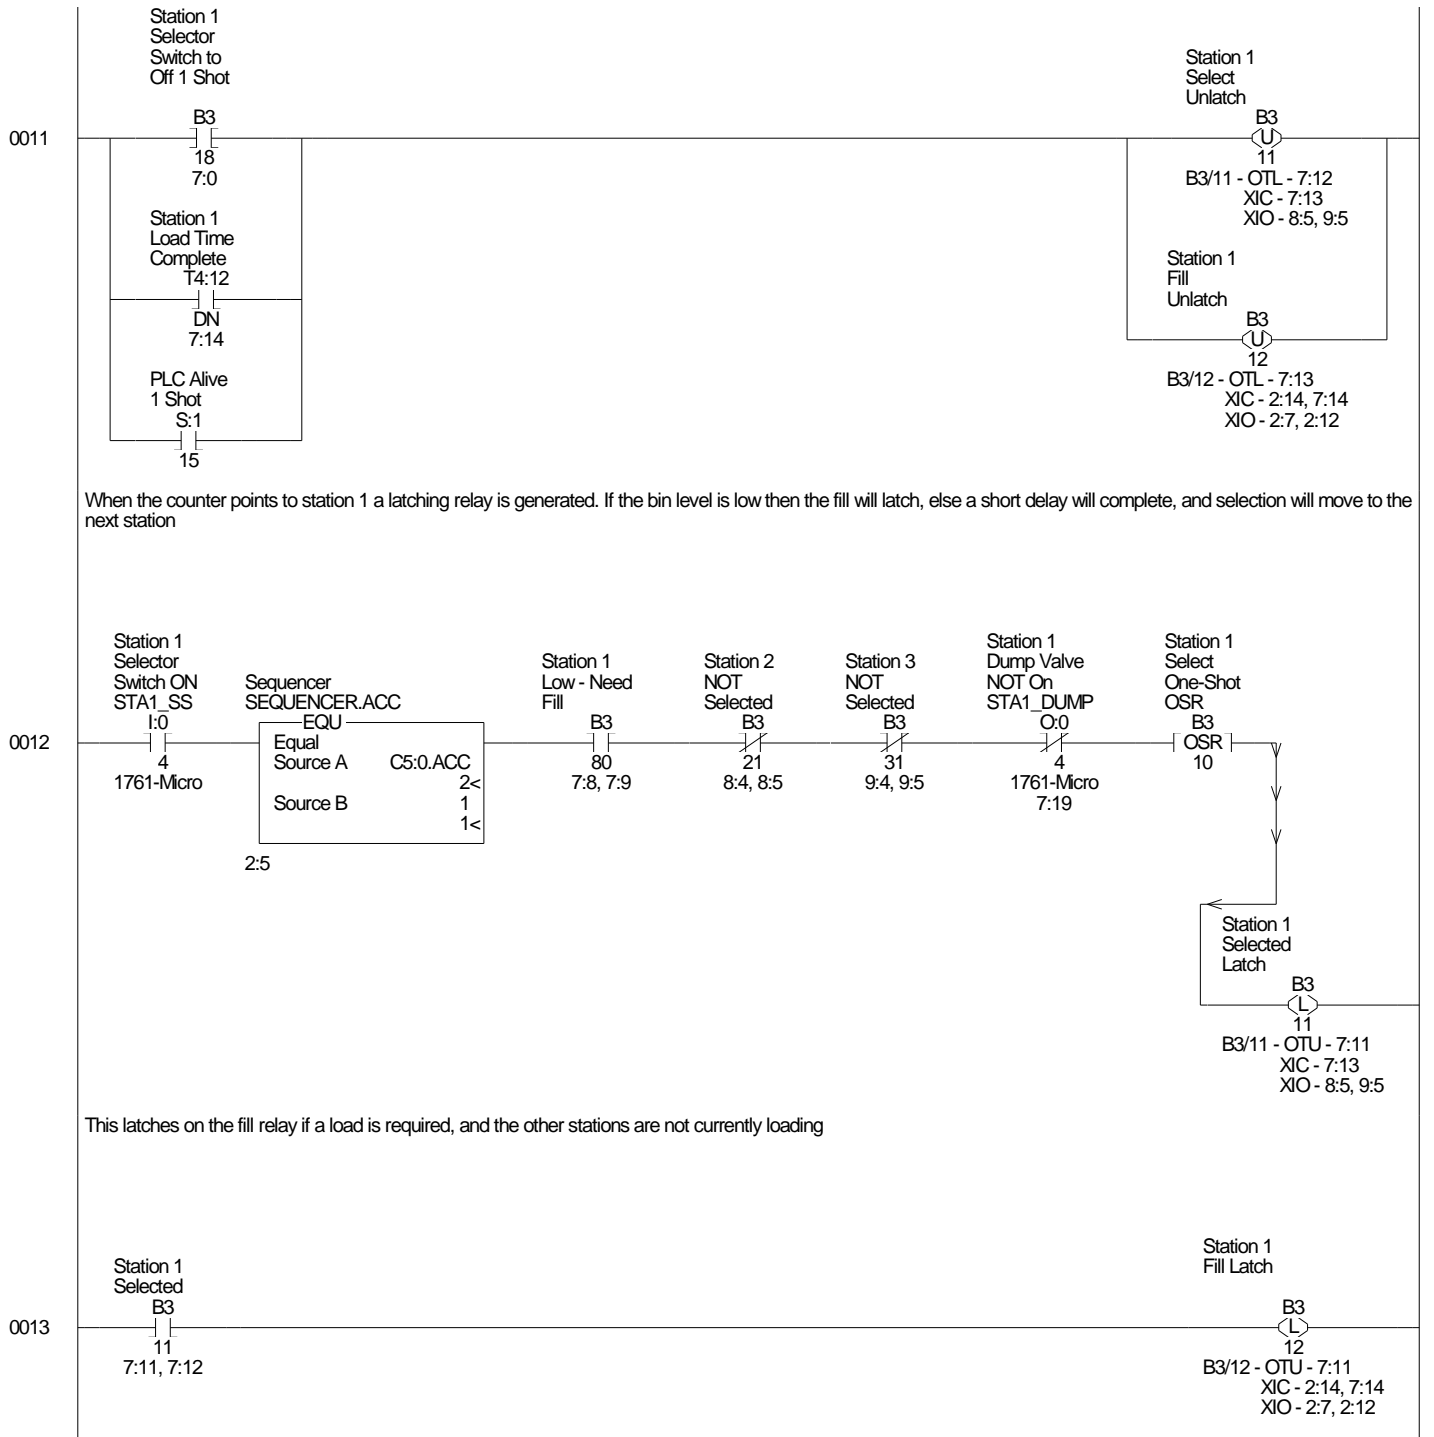

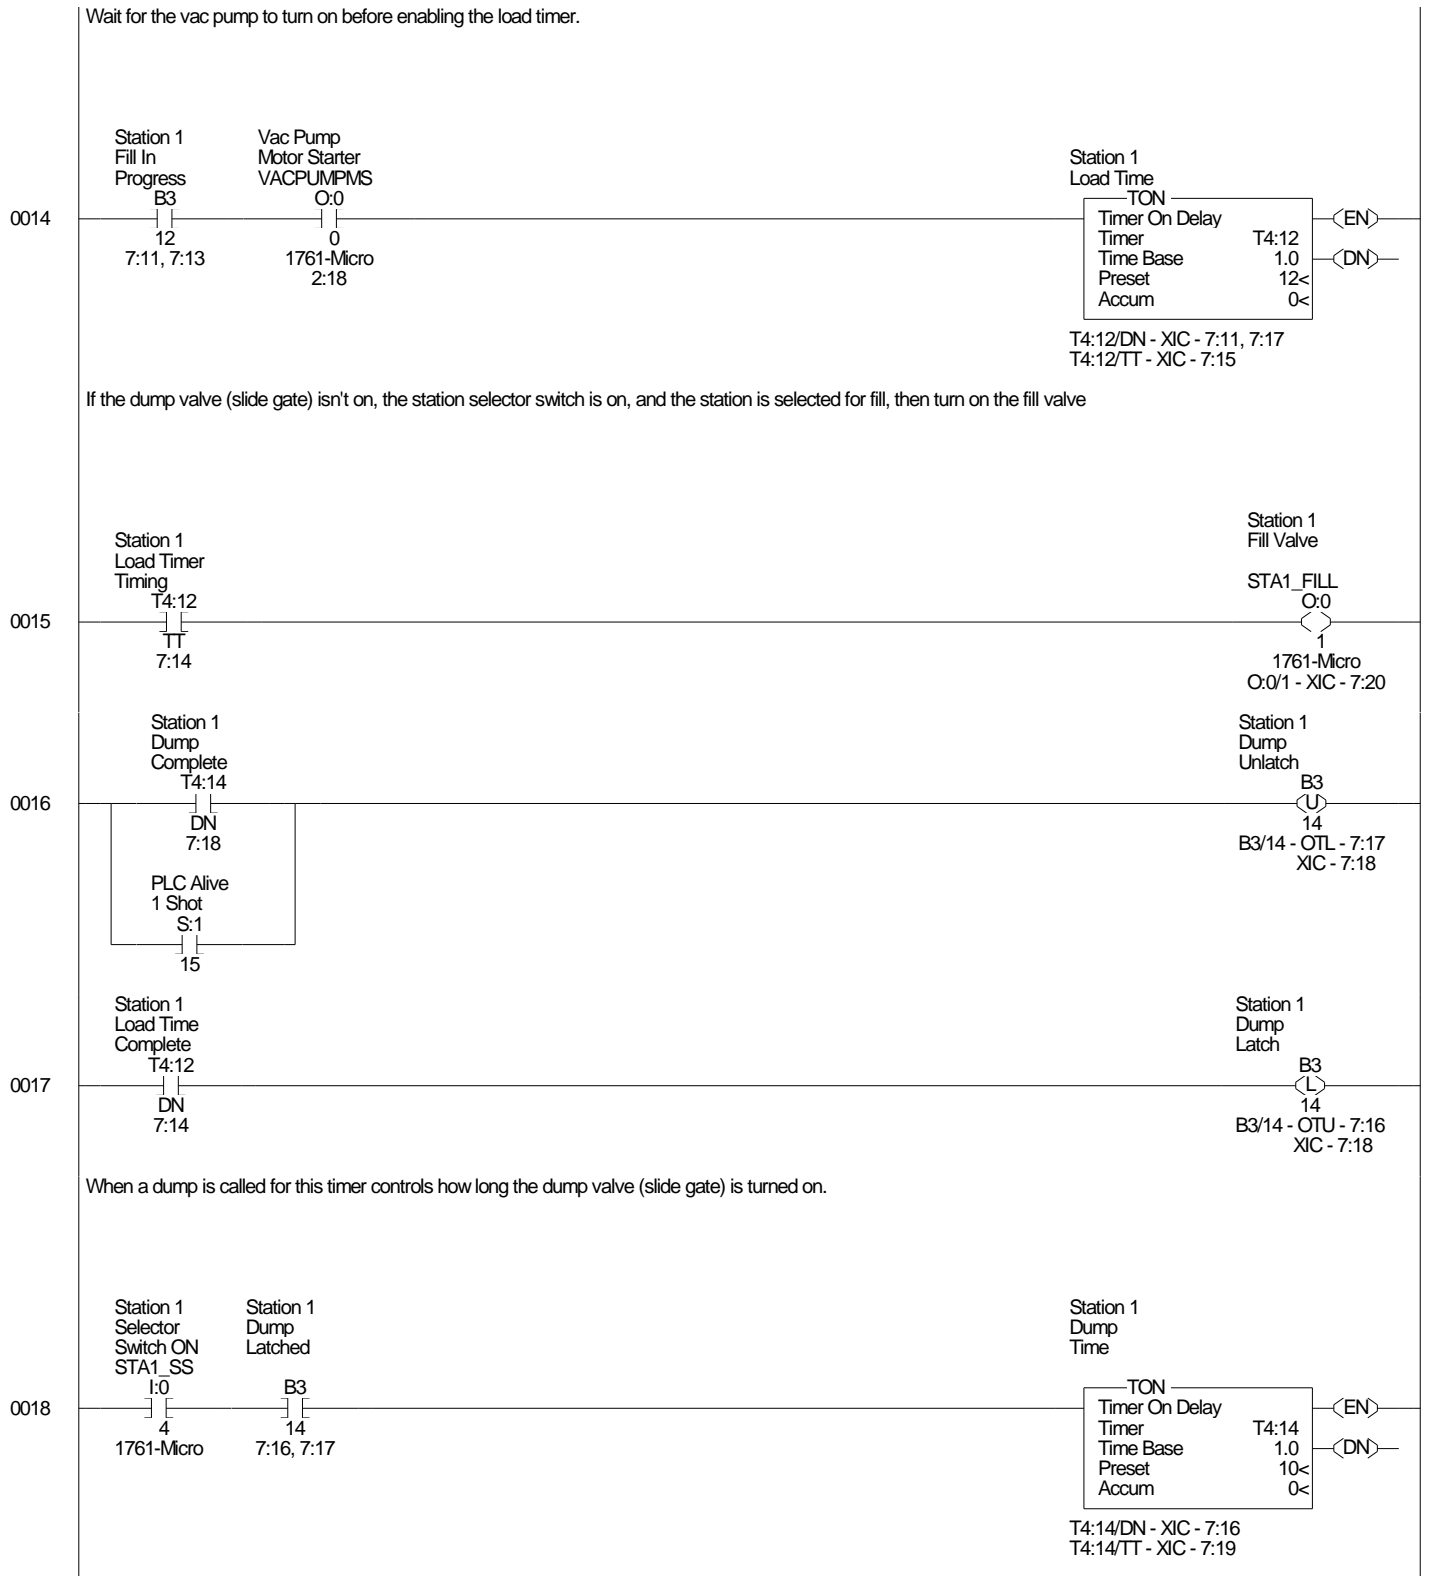

If station 1 level is high for less than half the time (3000 of 6000 - 30 in 60 seconds) then consider it low.

This retentive timer is reset once per minute, so can time out to a maximum value of 6000. Greater and less than comparisons are performed using the accumulated value at the one minute mark to determine whether Station 1 is below or above the high level sensor. Note: because it is evaluated only once per minute it will normally allow a load one cycle past the point where the low level pilot lamp turns off.

The dump valve (slide gate) is turned on during normal operation in the first line of this rung, when the selector switch is turned to 'Off' (for one last cycle) in the second line, and during system initialization in the third line.

Each time a fill is commanded this counter increments. If the fill is successful in restoring hopper level then it is reset. This counter is monitored and used by alarm logic that defines 'early warning' and 'serious condition' setpoints. Also reset if the counter ends up nearing 32767, although for most applications this will not be possible (the machine will run out of material well before this happens).

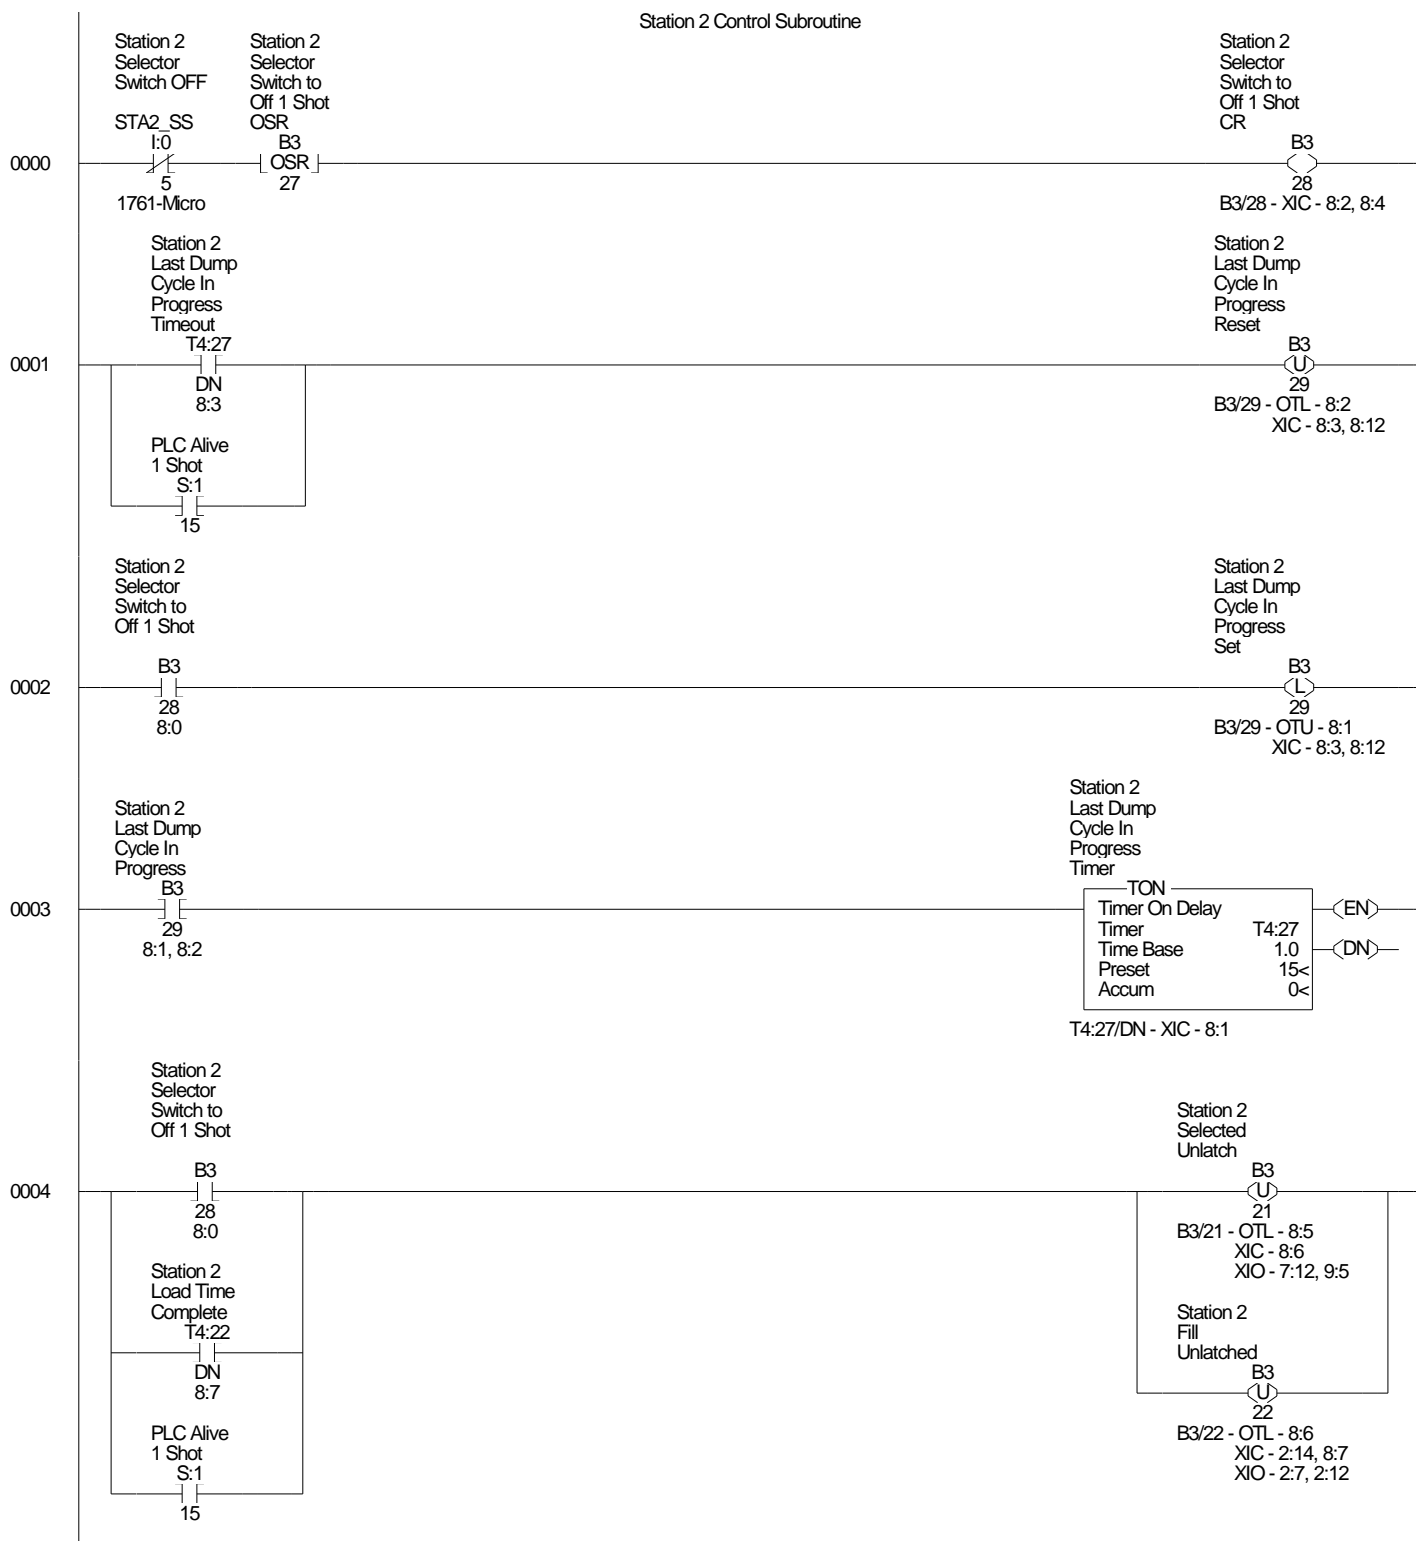

This is how long the level switch must show full before the 'bad fill' counter is reset.

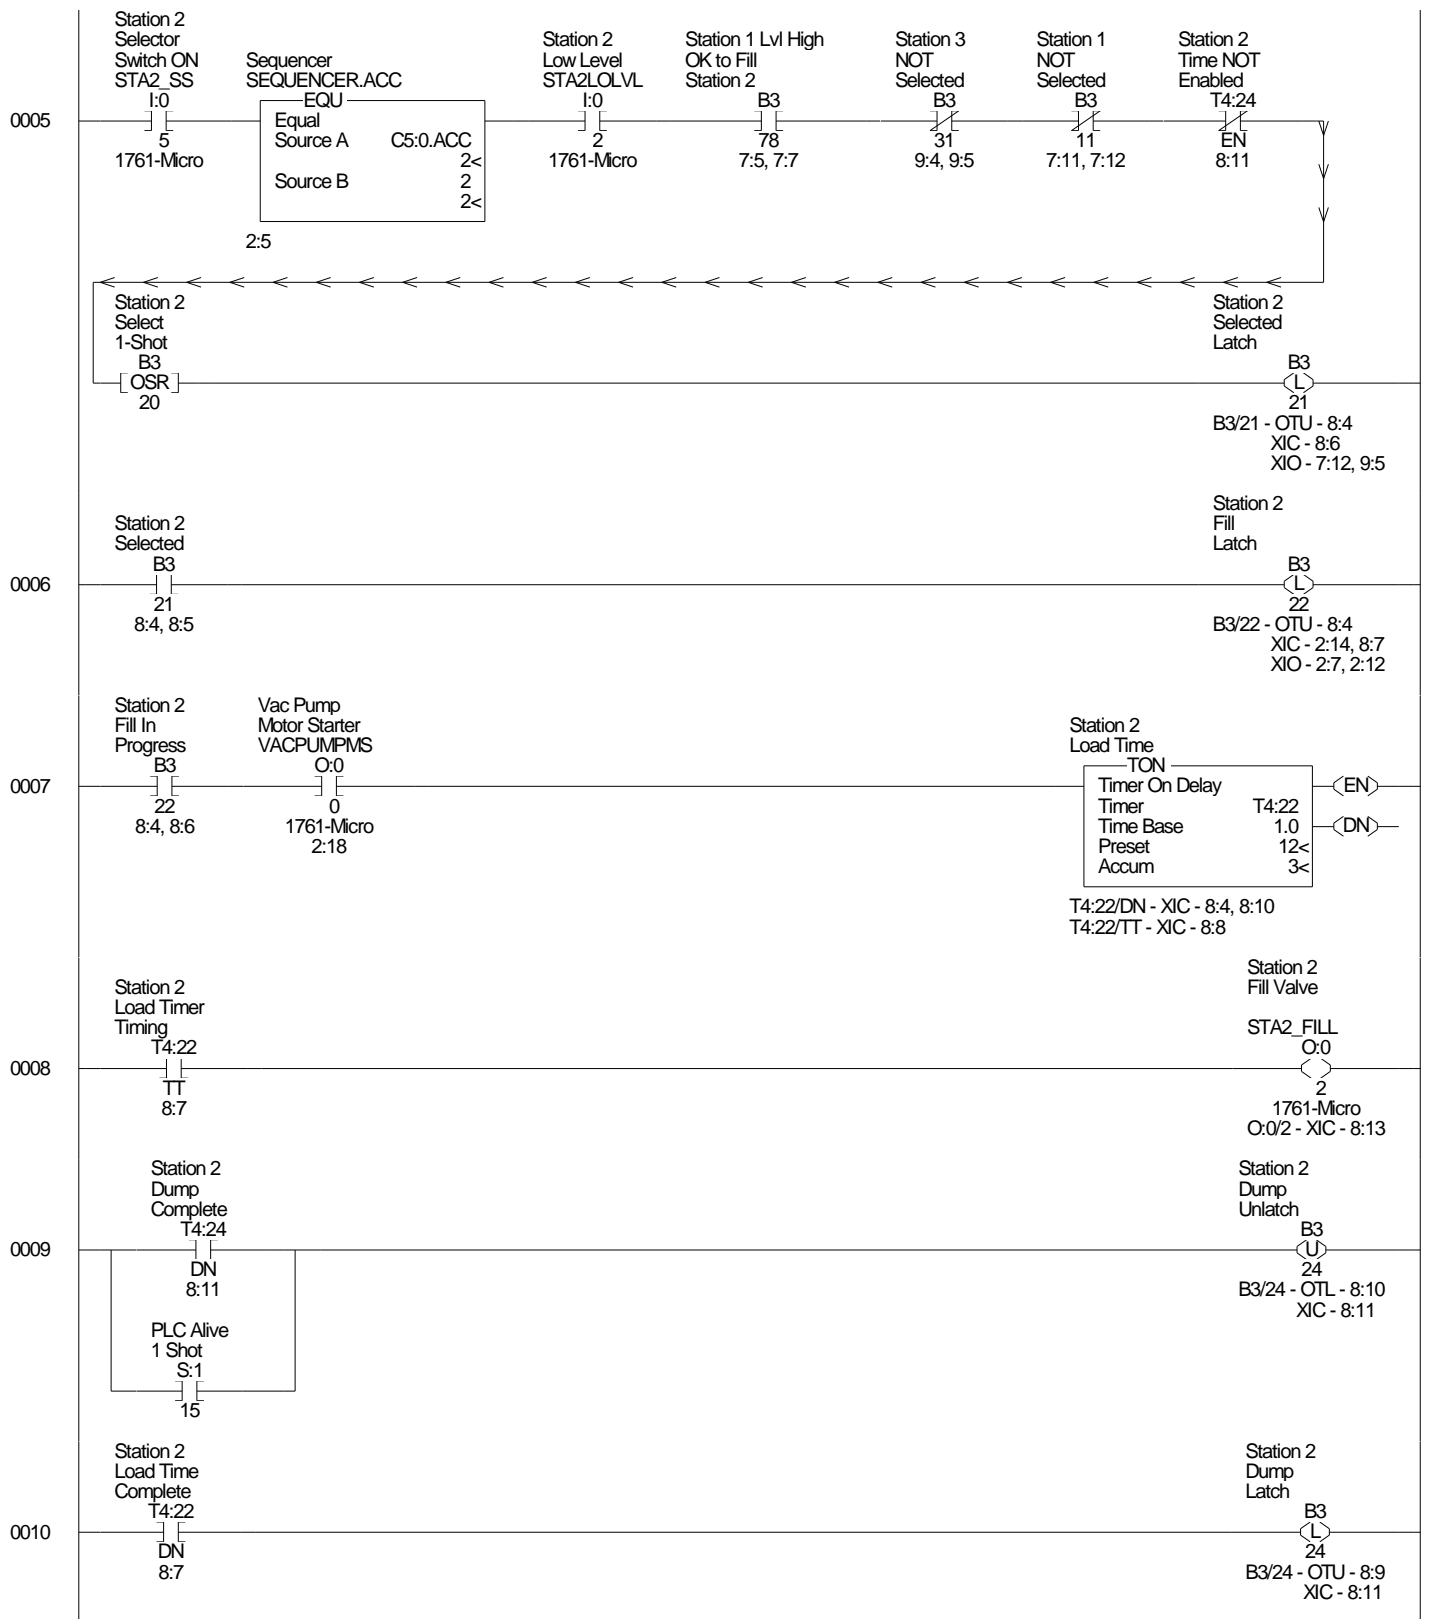

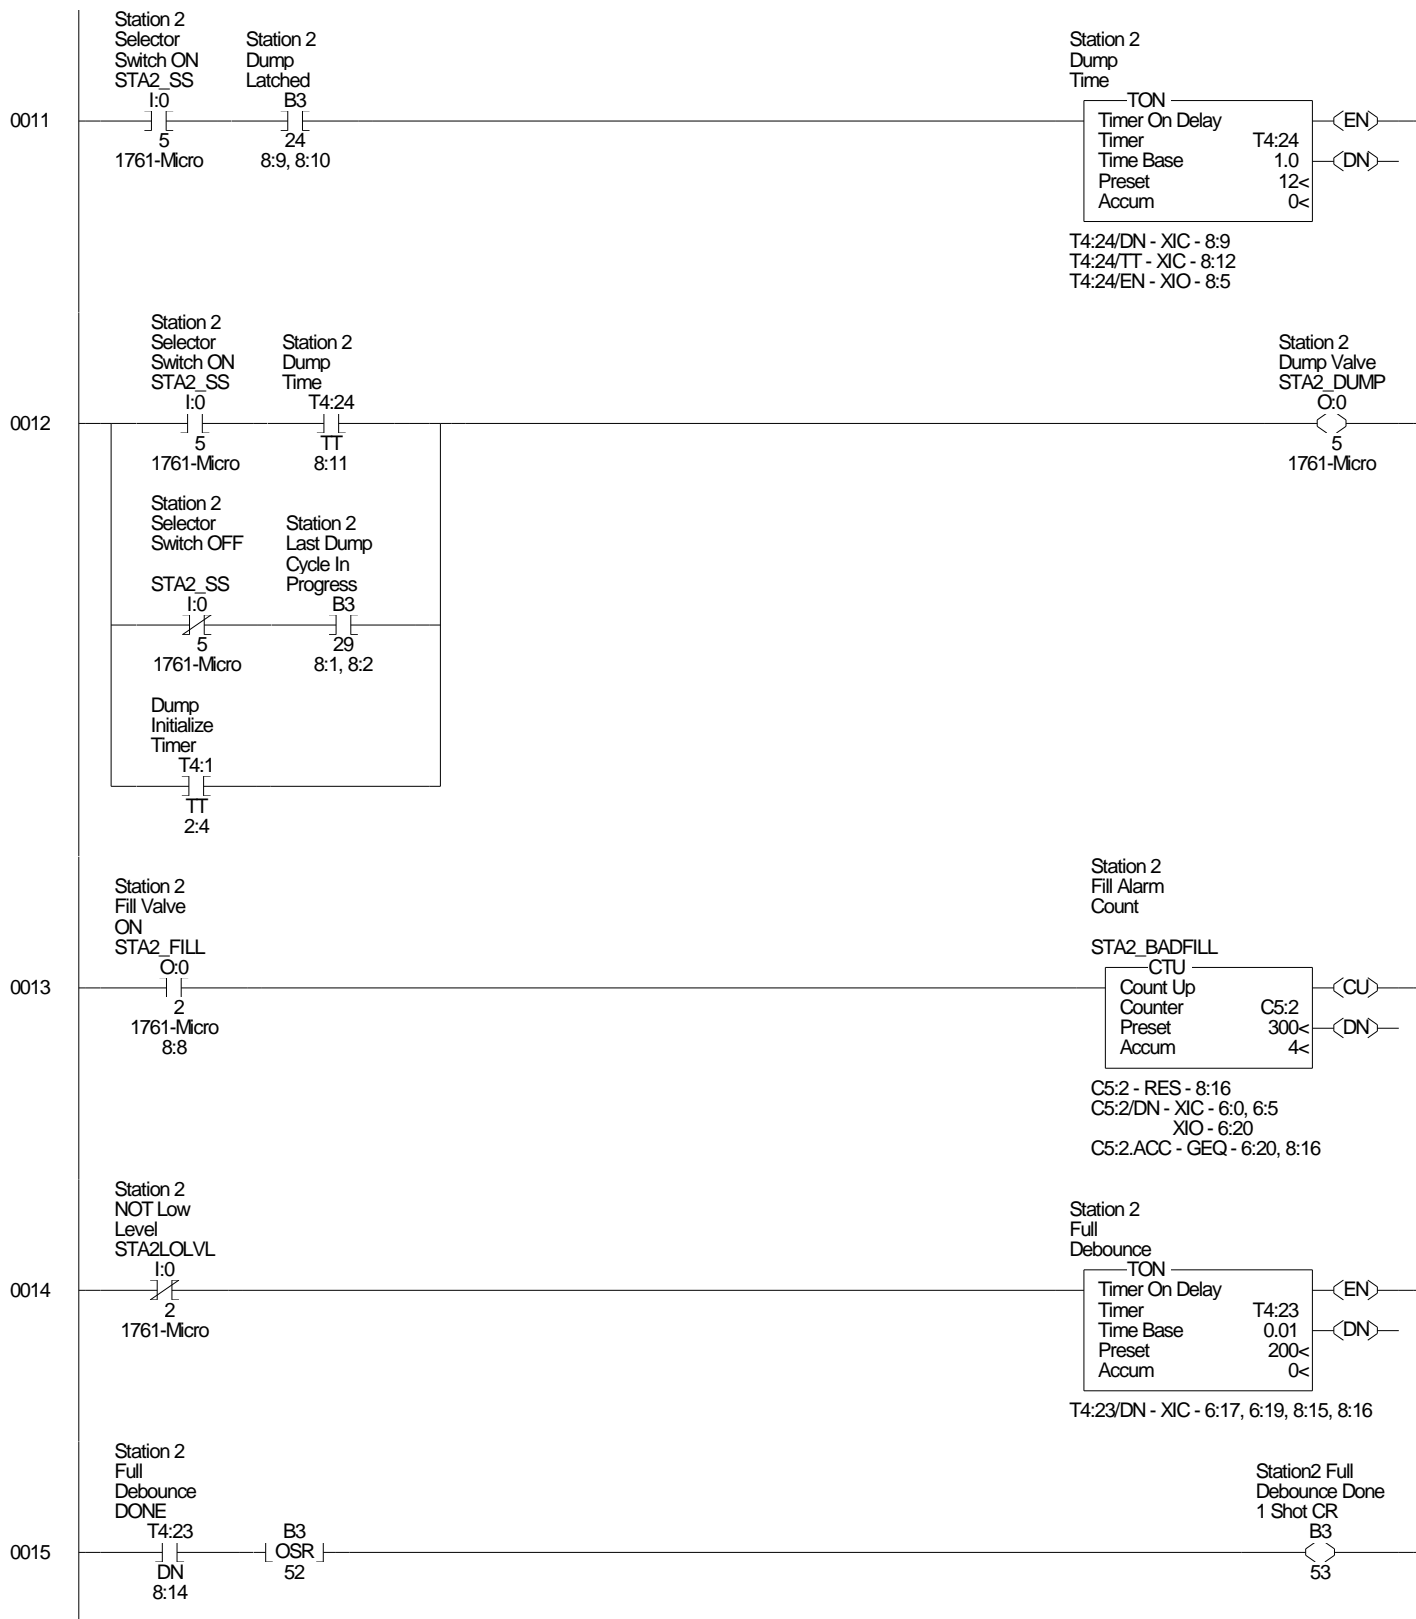

Each time a fill is commanded this counter increments. If the fill is successful in restoring hopper level then it is reset.
 This counter is monitored and used by alarm logic that defines 'early warning' and 'serious condition' setpoints.
 Also reset if the counter ends up nearing 32767, although for most applications this will not be possible (the machine will run out of material well before this happens).

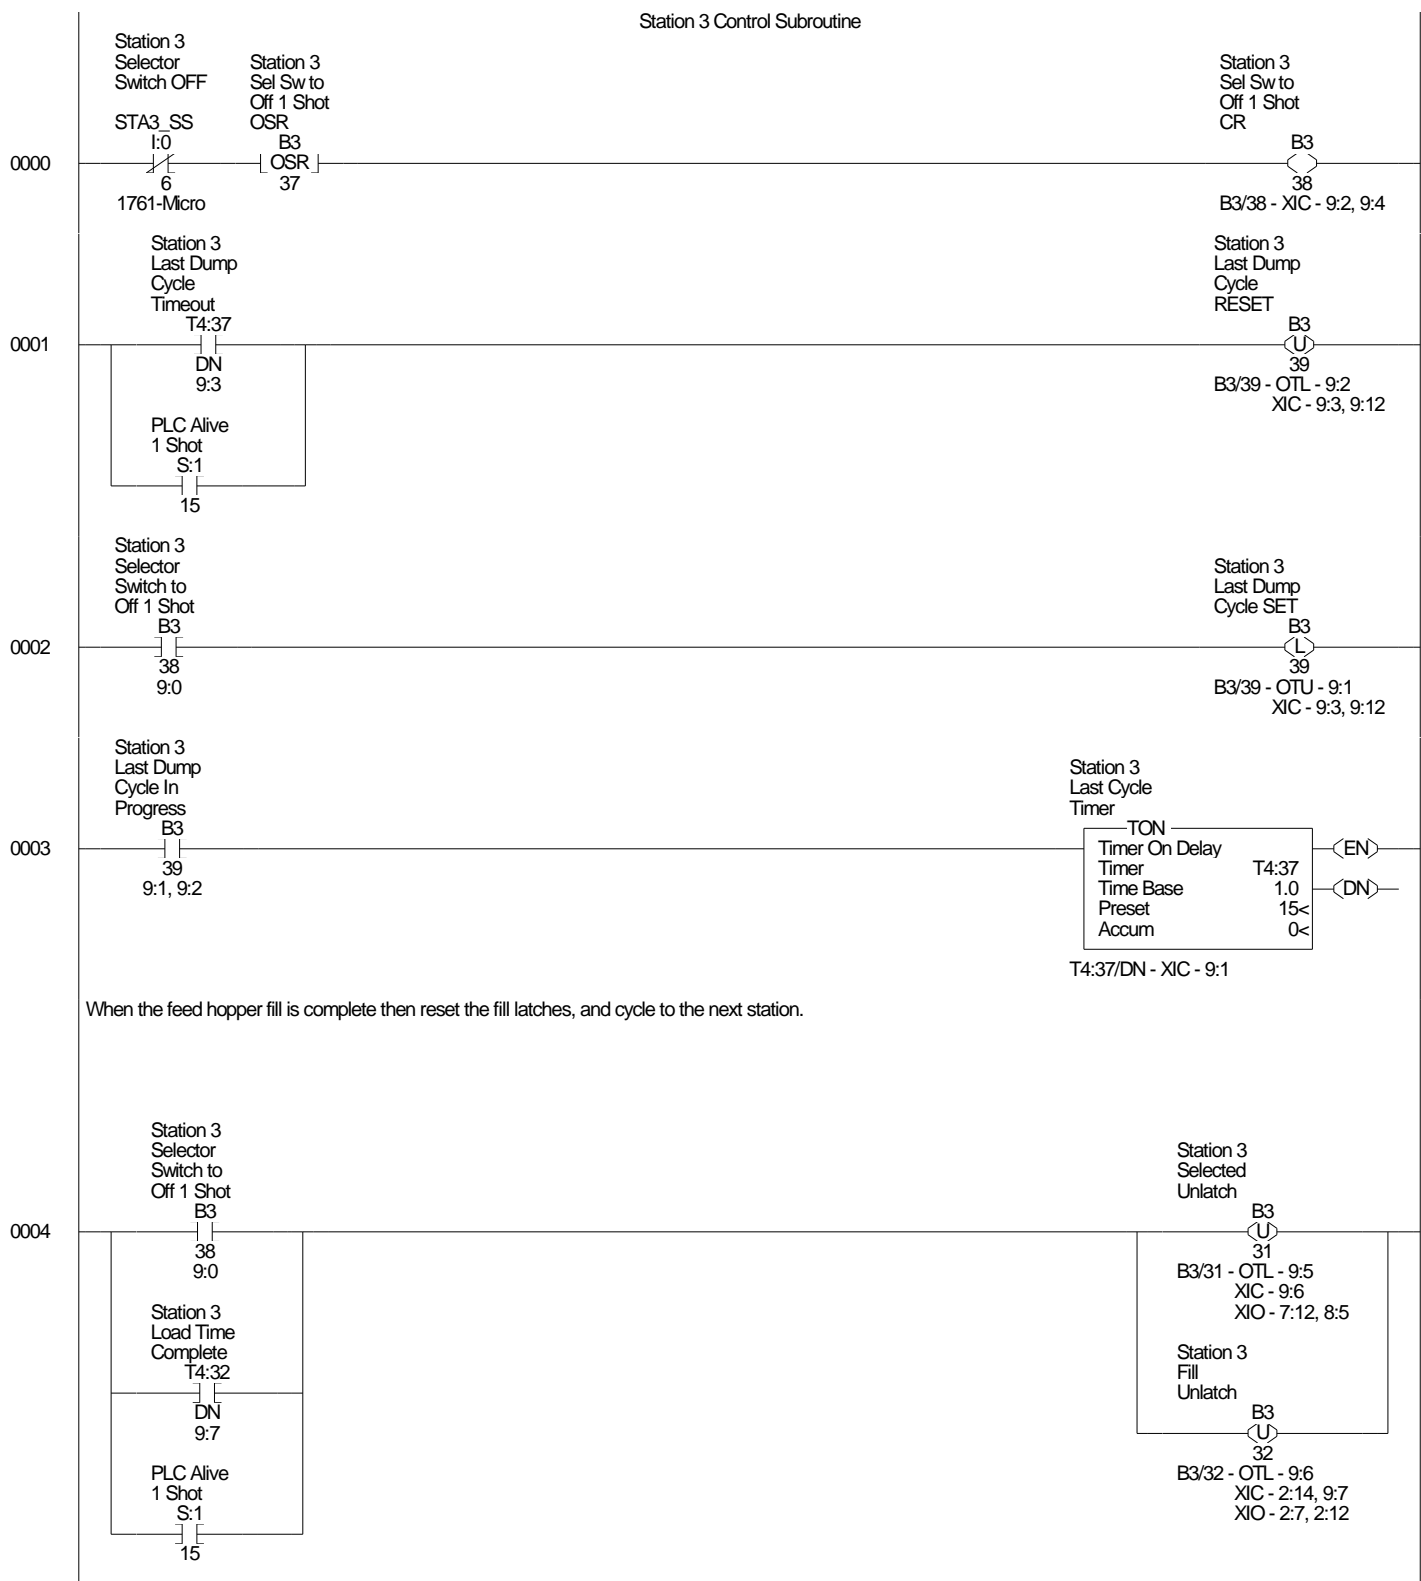

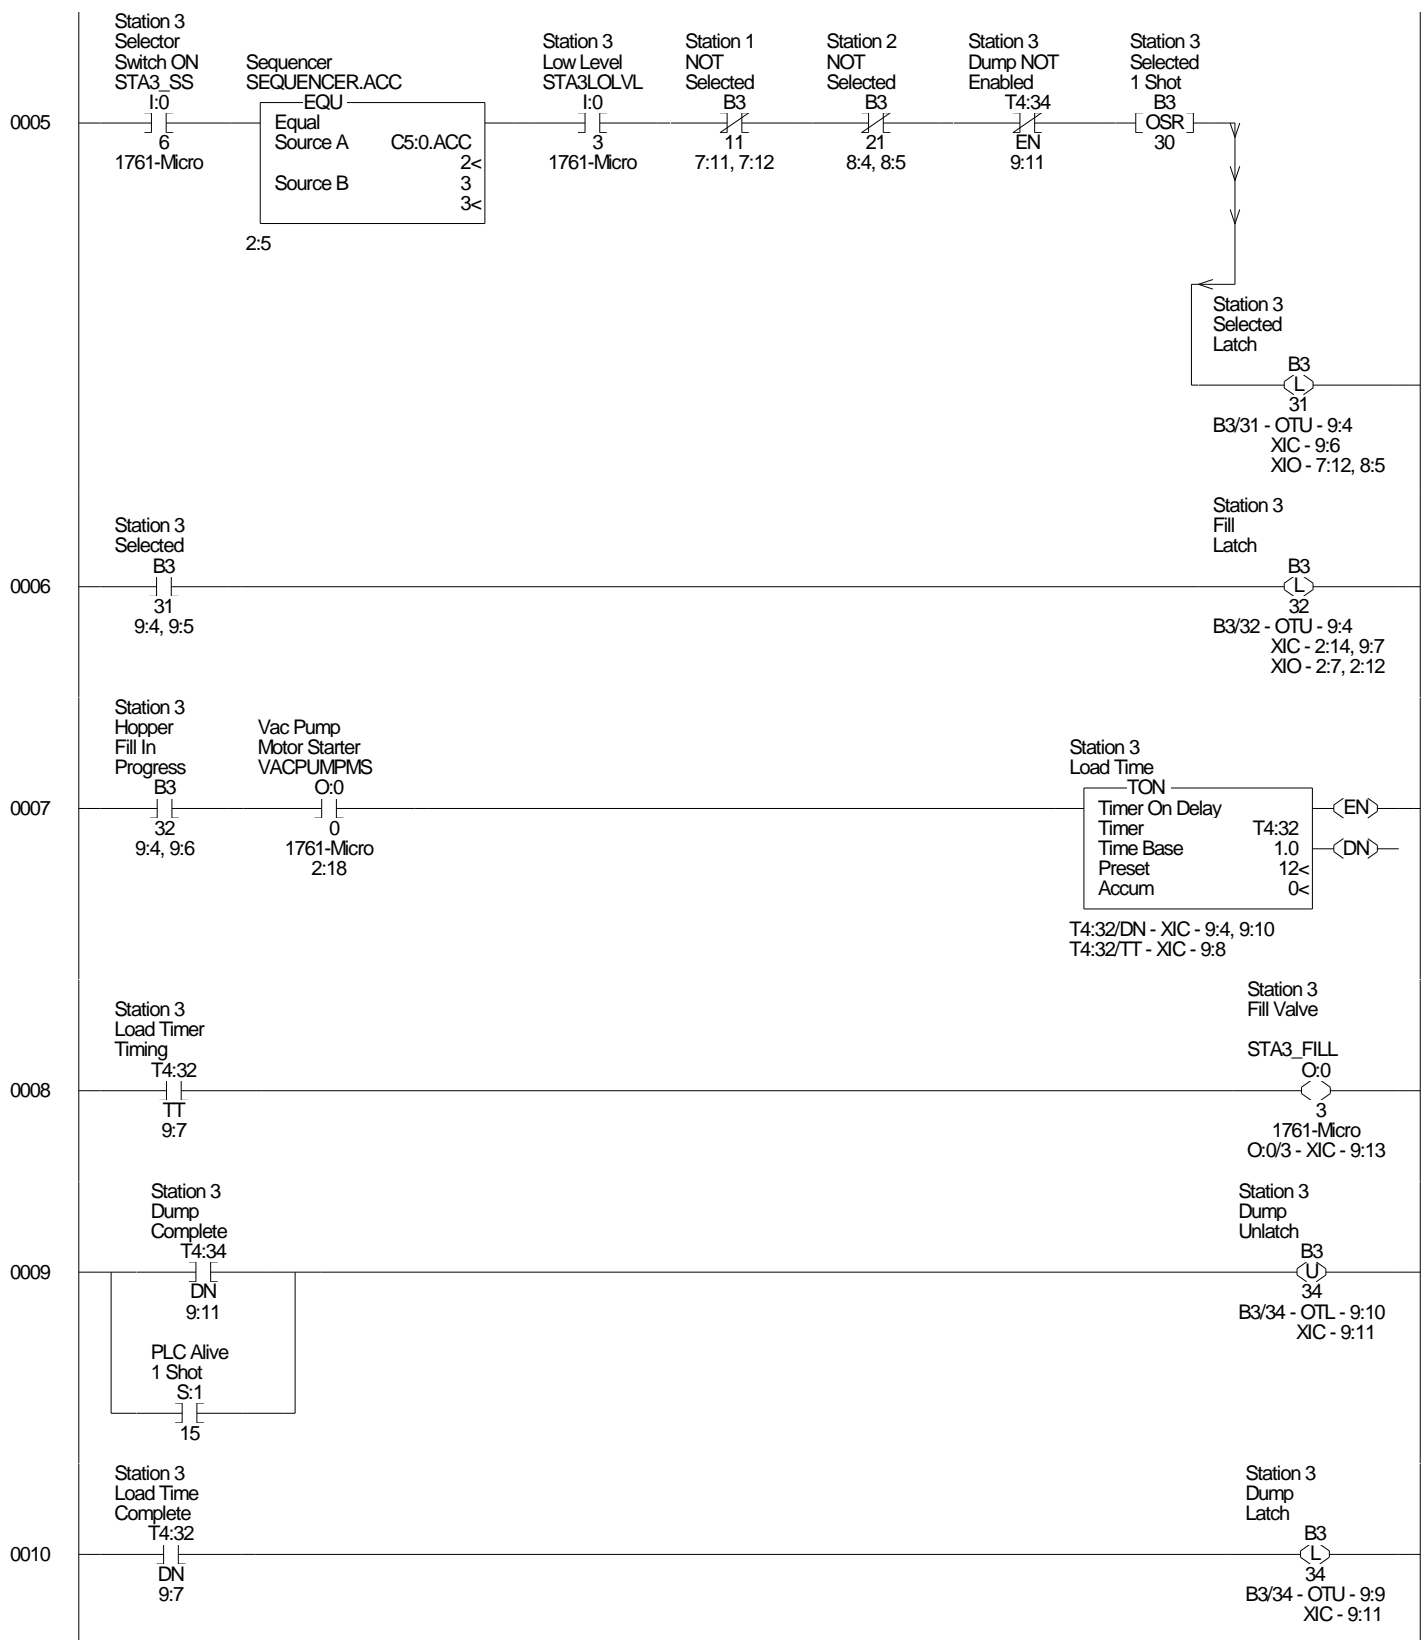

LAD 8 - STA2_CTRL --- Total Rungs in File = 19
